A. INTRODUCTION

This chapter is intended to provide a list of known pairs of isomorphous monomeric units in synthetic crystalline polymer systems; we shall regard as "isomorphism" the statistical copresence of different units within the crystallites. Additional information will be also given, namely:

(a) the approximate range of relative concentrations where isomorphism is observed;
(b) the chain conformation in the crystalline state, the type of isomorphism (see below);
(c) the physicochemical techniques used in the investigation (see Section B); and
(d) the references to the scientific contributions wherein the isomorphism is demonstrated, implied, or claimed.

Systems in which the molar fraction of either type of monomeric units does not exceed about 5% have been disregarded. Cocrystallization of hydrogenated and deuterated units has not been considered as relevant in this context either.

Although we are aware of the growing expansion and importance of copolymer systems producing mesophases (92), we have chosen to limit our list to isomorphism in the classical crystallographic sense. In particular, polymer systems were regarded as crystalline either (i) when off-meridional X-ray reflections appear on the nonequatorial layers, or (ii) if the sample is shown to undergo a transition to a mesophase system before melting, as may be revealed by DSC methods. Sometimes distinctions between real crystalline systems and mesophases may be difficult, such as in the case of several polyesters. In all instances in which some degree of uncertainty is implied, an asterisk has been inserted.

The isomorphous polymer pairs are subdivided according to the scheme already proposed in a review article on the subject (2). Two basic classes of macromolecular isomorphism were distinguished, namely isomorphism of whole homopolymer chains (Class 1) and isomorphism of monomeric units within copolymer chains (Class 2) (2,62,63). Class 1 may be further subdivided into three different subclasses: subclass 1.1, where the monomeric units differ in chemical constitution (copolymers in the usual sense) (Table 1.1); subclass 1.2, where the monomeric units have randomly opposite, nonsuperimposable configurations (Table 1.2); and subclass 1.3, where the monomeric units, although stereochemically identical, assume different conformations at random. In spite of the scientific relevance of the last subclass in the context of polymer structure, we have preferred to omit the corresponding table, in view of both, the relatively low relevance of the issue for many people interested in polymer isomorphism, and of the wide ensemble of polymers that are presumably affected by this crystallographic disorder under appropriate circumstances. Also, for the sake of greater generality, we have included in subclass 1.2 (Table 1.2) all the cases where the isomorphous units are related either by geometrical stereoisomerism or by random head-to-head, head-to-tail enchainment. Concerning Class 2, the subclass consisting of stereochemically identical chains with randomly opposite orientations of their axes within the crystal is not

reported for the same reasons given above for subclass 1.3. Consequently, only isomorphous systems consisting of stereochemically different homopolymer chains are reported. In each case, the two units of the isomorphous pair are separated by a slash.

From a crystallographic viewpoint the following two types of polymer isomorphism may be distinguished (the different monomeric units will be designated as A and B).

Type 1: Homopolymers A_N and B_M have a similar crystal structure, with sufficiently small differences in unit cell dimensions. Binary systems, whether copolymers or homopolymer mixtures, display the same structure at any intermediate composition, except for a continuous change in cell dimensions (isomorphism in a true sense). The homopolymer chains may possess helical conformations with slightly different ratios of monomeric units per helix pitch, in which case intermediate helix conformations should appear at intermediate compositions.

Type 2: The two homopolymers have different crystal structures and in each of them some amount of monomeric units of the other may be accommodated. Accordingly, the structure of the homopolymer corresponding to the monomeric units with prevailing amount is observed, and an abrupt change in the structure of the second homopolymer may take place at a suitable composition. The simultaneous presence of both structures may also be observed within some intermediate composition range, in analogy with low-molecular weight systems (isodimorphism).

These types correspond to the first two types of polymer isomorphism suggested by Natta (62,63), who also proposed a third type whenever one of the two homopolymers is unable to crystallize by itself. We have thought it expedient to include these caseswithin Type 2, particularly in view of the difficulty in ascertaining the complete inability of either homopolymer to crystallize. It should be added in this context that no assumption concerning thermodynamic stability of the following isomorphous systems is implicit here; on the other hand, the crystal packing and friction forces may well be strong enough in most cases as to prevent any appreciable solid–solid transformation.

Concerning the partition of the data within each separate heading (1.1, 1.2, etc.), we tried to conform to the standard criteria adopted in this book. Each monomeric unit is assigned to the class corresponding to the higher ranking monomer.

Whenever a crystallizable copolymer is constituted by a regularly repeating sequence of monomeric units, isomorphism is usually ruled out in view of the very presence of constitutionally repeating units, i.e., of an effective homopolymer.

Several vinyl copolymers show macromolecular isomorphism when the side groups are sterically ordered. If, as it always happens in the examples known hitherto, the order is of the isotactic type, we have called them "isotactic" (copolymers).

Several cases are known of polymers having long, regular side groups (comb-like copolymers or the like) that may promote crystallization in spite of lack of configurational order in the main chain. These systems are not considered as belonging to the present list if crystallization is basically due to regular packing of the side chains only.

Whenever the conformation of the chain skeleton may be described as a regular helix, we have used the symbolism recommended by the document "Terminology Relating to Crystalline Polymers" of IUPAC (1984) and adopted, e.g., by R. L. Miller in the chapter "Crystallographic Data for Various Polymers" of this book. As an example, the helical conformation of the crystalline isotactic copolymers of 3-methyl-1-butene and 4-methyl-1-pentene (see Ref. 14), corresponding to four monomeric units in one turn, each unit having two skeletal atoms, is designated as $2*4/1$. However, referring to the general notation p/q, we have not considered as helical those conformations where both p and q are equal to unity (i.e., one repetitive unit in one turn). In these instances, qualifications such as "extended", "planar zig-zag", etc. are used to characterize the conformation. Also, whenever the helix structure is not explicitly reported by the author, the general term "helical" is adopted.

It may happen that, for a given concentration of the two monomeric units, more than one crystalline phase is observed. Under these circumstances, the corresponding chain conformations are reported.

For a discussion of macromolecular isomorphism, see Refs. 2,90,91, and some of the papers quoted therein.

B. TECHNIQUES

XR	Qualitative evaluation of crystallinity by diffraction methods
XR1	Structural analysis by diffraction methods (including observation of continuous changes of lattice spacings)
MP	Optically determined melting point
TA	Thermal analysis (DSC, DTA, etc.)
DM	Dynamical–mechanical measurements (e.g., mechanical and dielectric relaxation experiments)
MA	Morphological analysis (electron microscopy, SAXS etc.)
D	Density determination by flotation techniques
IR	Infrared spectroscopy
ED	Electron diffraction
CA	Conformational analysis

C. TABLES OF ISOMORPHOUS PAIRS OF MONOMER UNITS

TABLE 1. ISOMORPHOUS UNITS WITHIN THE SAME MACROMOLECULES (COPOLYMERS)

Monomer giving isomorphous copolymers	Mol% of first component	Type of isomorphism	Chain conformation	Techniques	Refs.

A. DEFINITION OF MISCIBILITY

A rigorous definition of miscibility is used in the following tables. In order to be classified as miscible polymers, there must be some evidence in the literature that the polymers are miscible on a submolecular (segmental) scale. If the polymer mixture contains several phases, the polymers will be listed as miscible even if segmental miscibility data exists in only *one* of these phases, but this is noted under Comments in the Tables. Tables 1–7 list miscibility in the *amorphous* state. A polymer pair will be listed as miscible even if one or both of the polymers forms a single-component crystalline phase in the mixture; a note about the existence of crystallinity, however, is made under Comments. Evidence for miscibility of a polymer with only one microphase in a microphase separated block copolymer is also noted. In other cases, literature data indicated miscibility with a known block copolymer, but no data were shown which indicate whether the mixture still contained the second microphase. In those cases, no comments are made in these Tables, and readers will have to make judgements of their own. Since miscibility on a submolecular or segmental scale includes cocrystallization, some mixtures that have proven cocrystallization behavior are shown in Table 8.

There is some controversy in the literature about the dimensions of the submolecular scale of segment mixing that indicates true miscibility in the amorphous state of polymers. Followers of one school of thought feel that every segment of polymer A must be surrounded by the numbers of segments of polymers A and B whose fraction is governed by the volume fraction of the two polymers present in that phase. This is the random mixing assumption implicit in the Flory–Huggins theory of polymer solutions and mixtures. These ideas are much too rigorous for real solutions, even solutions of small molecules. It is well known that clustering occurs in real solutions, so that volume elements containing an unexpectedly large number of one of the solution components (in solutions of small molecules) or segments of one of the polymers (in polymer mixtures) can and do occur. Thus, data generated by some solid state NMR techniques and some fluorescence techniques that can show the proximity of two polymers over a distance of 1–2 nm have often been misinterpreted to show immiscibility in a miscible polymer system. In fact, data showing that a large proportion of the nearest neighbor segments of a particular polymer belong to the same polymer could simply indicate clustering in a homogeneous phase.

B. DATA COLLECTION

The following tables include information from the third edition of "Polymer Handbook", additional information from an incomplete polymer–polymer miscibility database compiled by one of us (SK), and the data from papers (but not patents) published in the English language and listed in "CA Selects–Polymer Blends" and Science Citation Index through December 1995 as compiled by one of us (SHG). Note that Table 8 contains less complete information for the earlier years than the other tables because most of the information in this table comes from the incomplete database. The inclusion of patents and papers in languages other than English by SHG would have necessitated a great deal more time and additional data compilers.

C. ARRANGEMENT OF THE TABLES

The following eight tables have essentially the same format as those compiled for the third edition of "Polymer Handbook". Each table contains a particular mixture only once. The column labeled "Polymer I of" is an alphabetical listing. The column labeled "Polymer II of" is an alphabetical listing of the polymers miscible with the appropriate polymer from the first column. The common names of polymers were used whenever possible; sometimes the Chemical Abstracts or IUPAC names of polymers also appear. Unfortunately, we could not cross-list the many possible names of the polymers. Thus, it may be necessary to look for a particular polymer under several names in these tables.

The column labeled Methods very briefly indicates the method(s) used by the experimenters to determine miscibility in amorphous phases. A large number of such methods exist, but two of these are most commonly used. One of these involves the determination of glass transition temperatures (T_g's) by methods such as DSC, DTA, dynamic mechanical measurements, dilatometry, or other methods. The observation of a single T_g for the amorphous portion of a polymer mixture, especially if it is intermediate between those of the constituent polymers and varies monotonically between these values as the mixture composition changes, has generally been considered a reliable indication of a miscible polymer pair. This method is difficult to use when the T_g's of the constituent polymers are close together, perhaps within 10°C of each other. Furthermore, the glass transition region of a miscible polymer pair is often broader than that of the unmixed polymers. Some experimenters have interpreted this as an indication of two overlapping glass transition regions, but we have taken the existence of such a broad glass transition region as an indication of miscibility. We feel that a broad glass transition region probably indicates the existence of composition fluctuations rather than two overlapping T_g's.

The criterion of sample clarity has often been used as an indication of miscibility. This criterion will not work if the constituent polymers have the same refractive index or if they are so immiscible that they form phases so large that they do not scatter light appreciably. Furthermore, semicrystalline mixtures are always turbid, even if their amorphous phases are completely miscible. In addition, on at least one occasion, a set of polymers was turbid at low temperatures, clear at intermediate temperatures, and turbid again at high temperatures only because their refractive indices became almost identical at the intermediate temperatures.

All single methods, not all of them described here, of determining polymer–polymer miscibility sometimes give ambiguous results. Unless many experimenters have used a variety of methods to determine miscibility, the inferences drawn from the data may be wrong. This is one of the reasons for listing the methods used and the references that describe the experiments, results, and interpretation. Some of the mixtures listed in these tables, especially when only a single mixture has been reported in a single reference, may turn out to be less miscible than stated. This is especially possible because some of the methods that were used in the original investigations do not necessarily probe miscibility as such. For example, a negative volume change on mixing, that is, a shrinkage on mixing, could possibly be observed if each of the coexisting phases contains both polymers, though in different proportions, and if each of the coexisting phases has a negative volume change on mixing. Also, FTR methods generally involve the observation of absorption band shifts due to hydrogen bonding between polymers; however, this hydrogen bonding could conceivably occur on phase boundaries or within coexisting phases each of which contains both polymers, but in different proportions.

The Comments column in the Tables indicates compositions of copolymers, whether the samples were semicrystalline, and other relevant data.

The eight tables are:

1. Chemically dissimilar polymer pairs miscible in the amorphous state at room temperature. Some of these polymers may be copolymers, but the polymer pairs may not have any monomer units in common. One or both of the polymers may be semicrystalline.
2. Polymer pairs containing one monomer in common (at least one of these must be a copolymer), miscible in the amorphous state at room temperature. One or both of the polymers may be semicrystalline.
3 Chemically, dissimilar polymer triads and tetrads miscible in the amorphous state at room temperature. It seemed reasonable to place mixtures of three or four polymers that were miscible in a separate table.
4. Polymer pairs miscible in the amorphous state at room temperature. Molecular weight dependence investigated. These are usually polymer pairs that are miscible when the molecular weights are low and immiscible as when the molecular weights are increased.
5. Polymer pairs that appear to have high temperature miscibility although immiscible at or below room temperature (Upper Critical Solution Temperature [UCST] behavior).

6. Polymer pairs miscible at room temperature that appear to have a lower critical solution temperature (LCST) above room temperature. These polymer pairs are also listed in one of the earlier tables, usually Table 1 or 2.
7. Polymer pairs that appear to have both lower and upper critical solution temperatures.
8. Polymer pairs that cocrystallize and form mixed crystals. These blends are generally composed of polymers with similar subunits that can substitute for each other in the same unit cells; this is generally called "isomorphous replacement". This Table is probably incomplete even though cocrystallization is expected to be rare.

Abbreviations

DSC	Differential scanning calorimetry
FTIR	Fourier-transform infrared spectroscopy
IGC	Inverse gas chromatography
LS	Light scattering
MW	Molecular weight (unspecified)
M_n	Number-average molecular weight
M_w	Weight-average molecular weight
NMR	Nuclear magnetic resonance spectroscopy
NRET	Nonradiative energy transfer fluoro-spectroscopy
PALS	Positron annihilation lifetime spectroscopy
SAXS	Small-angle X-ray scattering
SALS	Small-angle light scattering
SANS	Small-angle neutron scattering
SEM	Scanning electron microscopy
T_g	Glass transition temperature
T_m	Melting temperature
WAXD	Wide-angle X-ray diffraction

TABLE 1. CHEMICALLY DISSIMILAR POLYMER PAIRS MISCIBLE IN THE AMORPHOUS STATE AT ROOM TEMPERATURE

Polymer I of	Polymer II of	Method	Comments	Refs.
2-Acrylamido-2-methyl-propanesulfonic acid	Vinylpyridine	Single T_g	II was 2- or 4-vinylpyridine (2 blend systems); formed complexes	354
Acrylic acid	Acrylamide	NMR	Formed complexes	1012
	Acrylamide-*co*-*N*,*N*-dimethyl-acrylamide	Fluorescence study	Formed complexes; II had 6.0–55 mol% acrylamide	859
	Caprolactam (nylon 6)	Single T_g; WAXD	Semicrystalline	1140
	N,*N*-dimethylacrylamide	Fluorescence study	Formed complexes	859
	Ethylene glycol	Single T_g; FTIR; NMR	Semicrystalline when >50% II	374,712,953, 1115,1128
	Vinyl alcohol	FTIR; T_m-depression; NMR	Semicrystalline	197,1211,1255,1256,1257
	Vinyl methyl ether	Single T_g	Formed 1:1 complexes	160
	N-vinylpyrrolidone	NMR	Formed complexes	1128
Acrylic acid-*co*-ethylene	Caprolactam (nylon 6)	Single T_g	I had 19 wt.% acrylic acid	564
Acrylic acid-*co*-styrene	Caprolactone	Single T_g	I had 11.4–20.8 wt.% acrylic acid	383
	Ester	Single T_g	I had 20% acrylic acid; II was nylon 6, nylon 11 or nylon 12 (3 miscible blend systems)	471,884
	Ethyl methacrylate	Single T_g; IGC	I had 2.65–20 wt.% acrylic acid	72,1001
	Ethyl methacrylate-*co*-4-vinylpyridine	Single T_g; IGC	I had 20 mol% acrylic acid	1001
	Ethylene glycol	Single T_g	I had 21 wt.% acrylic acid	384
	Isobutyl methacrylate-*co*-4-vinylpyridine	Single T_g; IGC	I had 20 mol% acrylic acid	1001
	Methyl methacrylate	Single T_g	I had 8–20 wt.% acrylic acid	72,382,384
	n-Propyl methacrylate	Single T_g	I had 2.65–8.84 wt.% acrylic acid	70
	Vinyl methyl ether	Single T_g	I had 8–20 wt.% acrylic acid	576
Acrylonitrile-*co*-butadiene	Cellulose acetate-butyrate	Some compositions appeared homogeneous	–	30,249,452,651
	Chloroprene	Single T_g when I had 18% acrylonitrile; sorption of solvent vapors	Two phases in electron micrograph when I had 18% acrylonitrile may indicate a crystalline phase; two torsional transitions when I had ≥ 28% acrylonitrile	93,797
	Epichlorohydrin	Single T_g	II had 26–54 wt.% acrylonitrile	966
	Nitrocellulose	Transparent films when I had 28.6–44.4% acrylonitrile	Immiscible when I had 18.4% acrylonitrile	93,296,398,399 452
	Vinyl acetate-*co*-vinyl chloride	Single loss peak when ≤40% vinyl acetate in II; clear films for some mixtures of commercial polymers	Two loss peaks when ≥50% vinyl acetate in II	296,452 539,651

6. Polymer pairs miscible at room temperature that appear to have a lower critical solution temperature (LCST) above room temperature. These polymer pairs are also listed in one of the earlier tables, usually Table 1 or 2.
7. Polymer pairs that appear to have both lower and upper critical solution temperatures.
8. Polymer pairs that cocrystallize and form mixed crystals. These blends are generally composed of polymers with similar subunits that can substitute for each other in the same unit cells; this is generally called "isomorphous replacement". This Table is probably incomplete even though cocrystallization is expected to be rare.

Polymer I of	Polymer II of	Method	Comments	Refs.
	Vinyl chloride	Single T_g; IGC	I had 29–45 wt.% acrylonitrile	9,79,85,161,196, 452,484,520,561, 614,615,632,682,755 799,860,867,885,1186
	Vinyl chloride	Single T_g; microscopy	I was hydrogenated; I had 38 wt.% acrylonitrile	1191
	Vinyl chloride, head-to-head	Single T_g	I had 23.5–56.6 wt.% acrylonitrile	158
Acrylonitrile-*co*-butadiene-*co*-methyl acrylate	Ethylene-*alt*-maleic anhydride	Single T_g; microscopy	I was made from a copolymer of AN/MA (75/25) grafted onto BD/AN (70/30) copolymer	1156
Acrylonitrile-*co*-butadiene-*co*-styrene	Propylene-*co*-vinyl chloride	Single T_g	I was Blendex 701; II had 3.2 or 3.8% propylene; electron micrographs may indicate two phases	107
Acrylonitrile-*co*-methyl methacrylate	*N,N*-dimethylacrylamide	Single T_g; transparency	I had 70 wt.% acrylonitrile (AN)	648
	Maleic anhydride	Single T_g; transparency	I had 70 wt.% AN	648
	Vinyl chloride	Single T_g; transparency	II had 2–17 wt.% AN	1091
	N-vinylpyrrolidone	Single T_g; transparency	I had 70 wt.% AN	648
Acrylonitrile-*co*-methyl methacrylate-*co*-α-methylstyrene	Vinyl chloride	Single T_g	I had 8/58/34 or 32.3/8.1/59.6/ acrylonitrile/methyl methacrylate/ α-methylstyrene	93,1078
Acrylonitrile-*co*-α-methylstyrene	Alkyl methacrylate	Single T_g; transparency	I had 30 wt.% acrylonitrile (AN); II had an alkyl group of acetonyl, chloromethyl, 2-chloroethyl, 2-hydroxyethyl, 2-hydroxypropyl, methoxymethyl, methylthiomethyl or tetrahydrofurfuryl (8 miscible blend systems)	266,268,279
	n-Butyl methacrylate	Single T_g	I had 12 wt.% AN	152
	n-Butyl methacrylate-*co*-methyl methacrylate	Single T_g; transparency	I had 30 wt.% AN; II had 70 wt.% methyl methacrylate	289
	Ethyl methacrylate	Single T_g	I had 10–28 wt.% AN	152,277
	Ethyl methacrylate-*co*-methyl methacrylate	Single T_g; transparency	I had 30 wt.% AN; II had 30 or 60 wt.% methyl methacrylate	287
	Ethylene, chlorinated	Single T_g	Depended on AN and Cl contents	154
	Maleic anhydride-*co*-styrene	Single T_g	Region of miscibility was sensitive to MW	1011
	Methyl methacrylate	Single T_g	I had 10–37 wt.% AN; I had 30 wt.% AN and II was atactic or isotactic (Ref. 277); I had 6.5–30 wt.% AN (Ref. 1010)	152,277, 1010
	Methyl methacrylate-*co*-2,2,6,6-tetramethyl-piperidinyl methacrylate	Single T_g; transparency	I had 30 wt.% AN; II had ≥76.2 wt.% methyl methacrylate	272,274
	n-Propyl methacrylate	Single T_g	I had 17–20 wt.% AN	152
	Vinyl chloride	Single T_g	I had 30 wt.% AN; miscible when melt blended or cast from methyl ethyl ketone; immiscible when cast from tetrahydrofuran; I had 11.9–30 wt.% AN (Ref. 1010)	435,684, 1010
Acrylonitrile-*co*-*p*-methylstyrene	Acetonyl methacrylate	Single T_g; transparency	I had 43–61 wt.% AN	118
	2-Bromoethyl methacrylate	Single T_g; transparency	I had 14–61 wt.% AN	608
	n-Butyl methacrylate	Single T_g; transparency	I had 13.6 wt.% AN	285
	2-Chloroethyl methacrylate	Single T_g; transparency	I had 18.3–46 wt.% AN	613
	Chloromethyl methacrylate	Single T_g; transparency	I had 13–42 wt.% AN	263
	Cyclohexyl methacrylate	Single T_g; transparency	I had ≤22 wt.% AN	120
	2,6-Dimethyl-1,4-phenylene ether	Single T_g; transparency	I had ≤5.0 wt.% AN	275
	Ethyl methacrylate	Single T_g; transparency	I had 12–33 wt.% AN	285
	Methyl methacrylate	Single T_g; transparency	I had 12–34 wt.% AN	285
	Methylthiomethyl methacrylate	Single T_g; transparency	I had 19–34 wt.% AN	269
	n-Propyl methacrylate	Single T_g; transparency	I had 6–28 wt.% AN	285
	Tetrahydrofurfuryl methacrylate	Single T_g; transparency	I had 12–48 wt.% AN	286
	Tetrahydropyranyl-2-methyl methacrylate	Single T_g; transparency	I had 5–29 wt.% AN	119

TABLE 1. *cont'd*

Polymer I of	Polymer II of	Method	Comments	Refs.
Acrylonitrile-*co*-styrene	Acetonyl methacrylate	Single T_g; transparency	I had 33–58 wt.% AN	121
	Arylate	Single T_g	Miscibility the greatest when AN = 25%	7
	Arylate of tetramethylbisphenol-A	Single T_g	I had 4–13 wt.% AN	1048
	Benzyl methacrylate	Single T_g	I had 7.8–24.3 wt.% AN	1180
	2-Bromoethyl methacrylate	Single T_g; transparency	I had 10–58 wt.% AN	608
	Butylene adipate	Single T_g	I had 13–32.3 wt.% AN	228
	Butylene sebacate	Single T_g	I had 13–20 wt.% AN	228
	n-Butyl methacrylate-*co*-methyl methacrylate	Single T_g; transparency	I had 22 wt.% AN; II had 70 wt.% methyl methacrylate	289,405
	tert-Butyl methacrylate-*co*-methyl methacrylate	Single T_g	Miscibility depended on compositions of I and II	621
	Caprolactone	Single T_g; FTIR; microscopy; LS	I had 13–30 wt.% AN	228,295,458,565,729, 1021,1047,1097,1145,1185
	2-Chloroethyl methacrylate	Single T_g; transparency	I had 12.5–43 wt.% AN	613
	Chloromethyl methacrylate	Single T_g; transparency	I had 12–37 wt.% AN	262
	Copolyarylate of Tetramethylbis-phenol-A and tetrabromobis-phenol-A	Single T_g	Miscibility depended on compositions of I and II	
	Copolycarbonate of bisphenol-A and tetramethylbisphenol-A	Single T_g	I had ≤ 18 wt.% acrylonitrile; II had ≤ 22 wt.% bisphenol-A	431
	Cyclohexyl methacrylate	Single T_g; transparency	I had ≤ 20 wt.% AN	119
	Cyclohexyl methacrylate-*co*-methyl methacrylate	Single T_g	Miscibility depended on compositions of I and II	621
	2,6-Dimethyl-1,4-phenylene ether	Single T_g	I had ≤ 10.5 wt.% AN	457,1022
	2,6-Dimethyl-1,4-phenylene ether, benzoylated	Single T_g	I had 18 mol% AN; II had 35 or 86% benzoylated units	776
	Ethylene adipate	Single T_g	I had 25–28 wt.% AN	228
	Ethyl methacrylate	Single T_g; transparency	I had 5.5–28.0 wt.% AN (Ref. 229); I had 9–34 wt.% AN (Ref. 112)	112,229,489
	Ethyl methacrylate-*co*-methyl methacrylate	Single T_g; transparency	I had 22 wt.% AN; II had 30 or 50 wt.% methyl methacrylate	288
	Ethyl methacrylate-*co*-2,2,6,6-tetramethyl-piperidinyl methacrylate	Single T_g; transparency	I had 30 wt.% AN; II had ≤ 13.3 wt.% 2,2,6,6-tetramethyl-piperidinyl methacrylate	274
	Ethyloxazoline	Single T_g; transparency	I had 25–40 wt.% AN; two T_g's when I had 8, 23.5 or 70% AN	426,652
	Hexamethylene sebacate	Single T_g	I had 16.2 wt.% AN	228
	2-Hydroxyethyl methacrylate	Transparency	I had 22 wt.% AN	277
	2-Hydroxypropyl methacrylate	Single T_g; transparency	I had 22 wt.% AN	279
	Itaconic anhydride-*co*-methyl methacrylate	Single T_g	Miscibility depended on compositions of I and II	920
	Methoxymethyl methacrylate	Single T_g; transparency	I had 30 wt.% AN	269
	Methyl methacrylate	Transparency	I had 9.4–34.4 wt.% AN (Ref. 789); I had 9.5–28 wt.% AN (Ref. 229); I had 9–39 wt.% AN (Ref. 164)	56,164,229, 392,566, 598,651,670,741, 782,789
	Methyl methacrylate-*co*-*N*-phenylitaconimide	Single T_g	Miscibility depended on compositions of I and II	169
	Methyl methacrylate-*co*-phenyl methacrylate	Single T_g	Miscibility depended on compositions of I and II	621
	Methyl methacrylate-*co*-2,2,6,6-tetramethyl-piperidinyl methacrylate	Single T_g; transparency	I had 22 or 30 wt.% AN; II had ≤ 31.4 wt.% 2,2,6,6-tetramethyl-piperidinyl methacrylate	272,274
	Methylthiomethyl methacrylate	Single T_g; transparency	I had 9–36 wt.% AN	267
	Novolac	Single T_g	I had 25 wt.% AN; II was formaldehyde + 13/17/70 mol% *p-tert*-butylphenol/*m*-cresol/*o*-cresol	221
	Oxy-1,4-phenylene-sulfonyl-1,4-phenylene oxy-2,6-diisopropyl-1,4-phenylene isopropylidene 3,5-diisopropyl-1,4-phenylene	Modulus-temperature	I had 13–16% AN	685
	Phenyl acrylate	Single T_g	I had 14.6–34.1 wt.% AN (Ref. 717) or 11.5–32 wt.% AN (Ref. 1171)	717,1171, 1180

TABLE 1. *cont'd*

Polymer I of	Polymer II of	Method	Comments	Refs.
	n-Propyl methacrylate	Single T_g	I had 5.7–19.5 wt.% AN (Ref. 229) or 9–24 wt.% AN (Ref. 1090)	229, 1090
	Tetrahydrofurfuryl methacrylate	Single T_g; transparency	I had 9–48 wt.% AN	281,286
	Tetrahydropyranyl-2-methyl methacrylate	Single T_g; transparency	I had ≤31 wt.% AN	116
	Vinyl chloride	Single T_g	I had 11.5–26 wt.% AN	437
Acrylonitrile-*co*-vinylidene chloride	Caprolactone	Single T_g	I was usually Saran F (80% vinylidene chloride); semicrystalline when ≤70 wt.% I	31,825,887
	Hexamethylene terephthalate	Single T_g	Probably semicrystalline; I was Saran F(80% vinylidene chloride)	36
Allyl alcohol-*co*-styrene	Ester	Single T_g	I had M_W = 1.4–2.1 kg/mol and had 1.3–7.7 wt.% OH groups; II was butylene adipate, butylene sebacate, caprolactone, 1,4-cyclohexane dimethylene succinate, decamethylene sebacate, 2,2-dimethyl-1,3-propylene adipate or hexamethylene sebacate (7 blend systems); high OH content of I favored miscibility	46,869
Amic acid	3,3′-Diamino-4,4′-benzidine isophthalamide	Transparency; FTIR	I was PARC-TPI	1071
	Phenol–formaldehyde	Clear before and after curing	I was made from 4,4′-methylene-dianiline and pyromellitic dianhydride	1
	Imide	Single T_g	II was Polyimide P84; miscible over certain composition range	538
Amideimide	Novolac	Single T_g	I was made from rosin	466
	Resol	Single T_g	I was made from rosin maleic anhydride Diels–Alder adduct with 4,4′-diamino-diphenylmethane	468
	Shellac	Single T_g	I was made from rosin-imidoamino acid with 4,4′-diaminodiphenylmethane	469
n-Amyl methacrylate	Vinyl chloride	Single T_g; transparency	–	319,649,812,850
	Vinyl chloride, chlorinated	Single T_g; transparency	II had 65 or 68 wt.% Cl	319,810
	Vinyl chloride-*co*-vinylidene chloride	Single T_g; transparency	II was Saran, ≥ 80% vinylidene chloride	407,812
Aramide	Amide	Single T_g	I was made from 2,2,4-trimethyl-1,6-hexanediamine and terephthalic acid (Trigamid T); semicrystalline; II was nylon 6, nylon 6,6, nylon 6,12, nylon 6,9 or nylon 6,10 (5 miscible blend systems)	211,212, 595
	Butylene terephthalate	Single T_g	I was Trogamid T; semicrystalline	596
	Caprolactam-*co*-laurolactam	Single T_g	I was Trogamid T; II had 43.8–55.6 mol% caprolactam; semicrystalline	213,214
	Caprolactam-*co*-2-pyrrolidinone	Single T_g	I was Trogamid T; II had 93.5 mol% caprolactam; semicrystalline	213,214
	Copolyester	Single T_g	I was Trogamid T; II was made from 1,4-cyclohexanedimethanol/ethylene glycol/terephthalic acid (PETG 6763)	596
	Cycloaliphatic amide	Single T_g	I was Trogamid T; II was made from 1,4- and 1,3-benzenedicarboxylic acids and a mixture of 1,6-hexanediamine and bis(4-aminocyclohexyl)methane (Bexloy AP C-803)	212
	Ethylene terephthalate	Single T_g	I was Trogamid T; semicrystalline	596
Aramide	Amide	Single T_g	I was made from 1,6-hexanediamine and a mixture of isophthalic and terephthalic acids (Zytel 330); semicrystalline; II was nylon 6, nylon 6,6, nylon 6,9 or nylon 4,6 (4 miscible blend systems)	212,213
	Cycloaliphatic amide	Single T_g	I was Zytel 330; II was Bexloy AP C-803	212
Aramide	Amide	Single T_g; T_m-depression	I was poly[2,2′-bis(trifluoromethyl)-4,4′-biphenylene dicarboxamide]; II was nylon 6, nylon 4,6, nylon 6,6, nylon	1013

TABLE 1. *cont'd*

Polymer I of	Polymer II of	Method	Comments	Refs.
			6,9, nylon 6,10 or nylon 11 (6 blend systems)	
Arylate	Aramide	Single T_g	I was made from bisphenol-A and a mixture of terephthalic acid/isophthalic acid/5-*tert*-butyl-isophthalic acid = 44/44/12 (Polyarylate C); II was Trogamid T	188
	Aramide-S	Single T_g	I was Polyarylate C; II was made from 5-*tert*-butylisophthalic acid/isophthalic acid 90/10 and 1,12-diaminododecane (Aramide-S)	189
	Aramide-M	Single T_g	I was made from bisphenol-A and a mixture of terephthalic acid/isophthalic acid/5-*tert*-butyl-isophthalic acid = 42.5/42.5/15 (Polyarylate D); II was made from adipic acid and *m*-xylene-diamine/hexamethylene diamine 80/20 (Aramide-M)	189
	Aramide	Single T_g	I was Polyarylate D; II was Trogamid T	189
	Aramide-S	Single T_g	I was Polyarylate D; II was Aramide-S	189
	Aramide-M	Single T_g	I was made from bisphenol-A and a mixture of terephthalic acid/isophthalic acid/5-*tert*-butyl-isophthalic acid = 37.5/37.5/25 (Polyarylate E); II was Aramide-M	189
	Aramide	Single T_g	I was Polyarylate E; II was Trogamid T	189
	Aramide-S	Single T_g	I was Polyarylate E; II was Aramide-S	189
	Aramide	Single T_g	I was made from bisphenol-A and a mixture of terephthalic acid/5-*tert*-butylisophthalic acid 50/50 (Polyarylate F); II was Trogamid T	189
	Aramide	Single T_g	I was Polyarylate F; II was Aramide-S	189
	Carbonate of bisphenol-A	Single T_g	I was made from bisphenol-A and a mixture of terephthalic acid/isophthalic acid 50/50 (Ardel D-100); miscibility arised from transesterification	687
	Copolyester	Single T_g	I was Ardel D-100; II was made from cyclohexane dimethanol and terephthalic acid/isophthalic acid (80–87% tere) (Kodar A-150) and another copolymer with tere/iso ratio of 70/30	687
	Copolyester	Single T_g	I was Ardel D-100; II was made from cyclohexane dimethanol, ethylene glycol and terephthalic acid (molar ratio 1:2:3, PETG-6763)	291,687
	Ethylene terephthalate	Single T_g	I was Ardel D-100; miscibility arised from transesterification	687
	Hydroxyether of bisphenol-A (Phenoxy)	Single T_g	I was Ardel D-100; miscibility arised from transesterification	687
Arylate of tetramethyl-bisphenol-A	Butylene sebacate	Single T_g	Semicrystalline	907
	Hexamethylene sebacate	Single T_g	Semicrystalline	906
Aryl ether ketone	Etherimide	Single T_g	I was made from 4,4′-difluoro-benzophenone and hydroquinone; II was Ultem 1000	334
	Etherimide	Single T_g	I was made from *p*-phenoxybenzoyl chloride; II was Ultem 1000	334
Aryl sulfone	Imide	Single T_g	I was Radel A; II was XU-218	375
γ-Benzyl glutamate	γ-Butyl glutamate	Dynamic mechanical methods; DSC	Miscible as random coils but not as α-helics	813
Bis(methyoxyethoxyethoxy) phosphazene	Acrylic acid-*co*-methyl methacrylate	Single T_g; transparency	II had 10, 20 or 30 mol% acrylic acid	1087
	Methacrylic acid-*co*-methyl methacrylate	Single T_g; transparency	II had 20 mol% methacrylic acid	1087
	Styrene-*co*-styrene-4-carboxylic acid	Single T_g; transparency	II had 75 mol% styrene	1087

TABLE 1. *cont'd*

Polymer I of	Polymer II of	Method	Comments	Refs.
	Styrene-*co*-*p*-vinylphenol	Single T_g; transparency	II had 78 mol% styrene	1087
	p-Vinylphenol	Single T_g; transparency	–	1087
Bis(methoxyethoxyethoxy-ethoxy)phosphazene	*p*-Vinylphenol	Single T_g; transparency	–	1087
3-Bromo-2,6-dimethyl-1,4-phenylene ether	*p*-Bromostyrene	Single T_g; microscopy	–	402
	p-Bromostyrene-*co*-styrene	Single T_g; microscopy	II had ≤ 85 mol% styrene	402
3-Bromo-2,6-dimethyl-1,4-phenylene oxide-*co*-2,6-dimethyl-1,4-phenylene ether	*p*-Bromostyrene	Single T_g; microscopy	I had ≤ 22 mol% 2,6-dimethyl-1,4-phenylene ether	402
	Styrene	Single T_g; microscopy	Miscible up to full bromination of I when I had MW ≤ 40 kg/mol and II had MW ≤ 30 kg/mol	402,530
2-Bromoethyl methacrylate	Ester	Single T_g	Semicrystalline; II was butylene adipate, caprolactone, 2,2-dimethyl-1,3-propylene adipate, 2,2-dimethyl-1,3-propylene succinate, ethylene adipate, or hexamethylene sebacate (6 miscible blend systems)	1137
	Tetrahydrofurfuryl methacrylate	Single T_g; transparency	–	606
p-Bromostyrene-*co*-styrene	2,6-Dimethyl-1,4-phenylene ether	Single T_g; microscopy	I had ≥ 53 mol% styrene	402
Butadiene	Butadiene	Single T_g	I was 1,4-polybutadiene; II had 63% 1,2-	701
	Diene-*co*-ethylene-*co*-propylene	Single T_g	Commercial samples; many mixtures had two T_g's	92,440,451
	Isoprene	Single T_g; microscopy; light scattering; NMR	Depended on microstructure; immiscible when I and II were both highly cis; I was deuterated (Ref. 335)	47,80,149,237,249, 335,520,542,548,549, 757,770,771,787,854, 901,1032,1063
Butadiene-*co*-styrene	*tert*-Butylstyrene	Single dynamic mechanical loss peak	I had 25% styrene; II had $M_w = 0.835$ kg/mol	138
	Glycerol ester of hydrogenated rosin	Single dynamic mechanical loss peak	I had 25% styrene; II had $M_w = 0.5$ kg/mol	139
1-Butene	1-Pentene	Single T_g	–	190
	Propylene	Single T_g	Semicrystalline	190,502,657
Butyl acrylate	Ethylene, chlorinated	Single T_g; transparency	II had 49.8 or 62.1% Cl; immiscible when II had 48.0% Cl	100
	4-Hydroxystyrene-*co*-styrene	Single T_g	I was *tert*-butyl; II had 28-66 mol% 4-hydroxystyrene	897
	Vinyl chloride	Single T_g; transparency	Some papers showed two T_g's (Refs. 812, 866) or phase separation in solution (Ref. 425)	425,655,812,845, 846,850,851 866
	Vinyl chloride-*co*-vinylidene chloride	Single T_g; transparency	II was Saran (≥ 80% vinylidene chloride)	812
Butyl acrylate-*co*-methyl methacrylate	Vinyl chloride	Single T_g; electron microscopy	I was Degalan V26(90% methyl methacrylate) (Ref. 886); I had 75% butyl acrylate) (Ref. 654)	654,886
Butyl methacrylate	*p*-(2-Hydroxy-hexafluoroisopropyl) styrene-*co*-styrene	Single T_g; transparency	II had 83.3–98.25 mol% styrene; immiscible when II had 99.0 mol% styrene	103,572,646, 807
	p-(2-Hydroxy-hexafluoroisopropyl)-α-methylstyrene-*co*-styrene	NMR	II had 1.5 mol% OH-containing monomer	89
	Vinyl chloride	Single T_g; transparency; miscible in solution	I was *n*-butyl, isobutyl or *sec*-butyl	319,425,649, 653,846,810,850
	Vinyl chloride-*co*-vinylidene chloride	Single T_g; transparency	II was Saran, ≥ 80% vinylidene; I was *n*-butyl, isobutyl or *sec*-butyl	409,812
n-Butyl methacrylate-*co*-methacrylic acid	Styrene-*co*-4-vinylpyridine	Single T_g; FTIR	I had 8 or 18 mol% methacrylic acid; II had 15, 22 or 28 mol% 4-vinylpyridine	985
n-Butyl methacrylate-*co*-4-vinylpyridine	Styrene-*co*-methacrylic acid	Single T_g; FTIR	I had 10.6, 18.9 or 26 mol% 4-vinylpyridine; II had 12, 24 or 29 mol% methacrylic acid	198,985
N-Butyl-3-hydroxymethyl carbazoyl methacrylate	ω-Hydroxybutyl-3,5-dinitrobenzoyl methacrylate	Single T_g	–	693
tert-Butylstyrene	Cyclohexyl acrylate	Single T_g; transparency	–	765
	Cyclohexyl methacrylate	Single T_g; transparency	–	765

TABLE 1. *cont'd*

Polymer I of	Polymer II of	Method	Comments	Refs.
	Isoprene	Single dynamic mechanical loss peak	I had $M_w = 0.835$ kJ/mol II was natural rubber	138
	3,3,5-Trimethyl-cyclohexyl methacrylate	Single T_g; transparency	–	765
Butylene adipate	Epichlorohydrin	Single T_g	Semicrystalline	223
	Hydroxyether of bisphenol-A (Phenoxy)	Single T_g; melt transparent; IGC	Semicrystalline when ≤ 60 wt.% II	332,1205
	Vinyl acetate-*co*-vinylidene chloride	Single T_g	II was Saran C ($\geq 80\%$ vinylidene chloride); semicrystalline	31
	Vinyl bromide	Single T_g	–	150
	Vinyl chloride	Single T_g	Semicrystalline when ≤ 70 wt.% II	900
Butylene dodecamethylene dicarboxylate	Vinyl chloride	Single T_g	Semicrystalline	872
Butylene 2,6-naphthalene dicarboxylate	Ethylene 2,6-naphthalene dicarboxylate	Single T_g	Blend had ≥ 80 wt.% I	1238
Butylene sebacate	Epichlorohydrin	Single T_g	Semicrystalline	223
	Vinyl chloride	Single T_g	Semicrystalline	872
Butylene terephthalate	Arylate	Single T_g; X-ray scattering	Semicrystalline	1040
	Butylene oxide-γ-butylene terephthalate	Single T_g; dielectric loss measurements; microscopy	II had 84 wt.% butylene terephthalate	554,703
	Copolyester	Single T_g	Semicrystalline when ≥ 25 wt.% I; II was CP-350(bisphenol-A-neopentyl glycol terephthalate)	768
	Copolyester	Single T_g	Semicrystalline; II was made from bisphenol-A and 1/1 or 1/3 tereph-thaloyl chloride/isophthaloyl chloride	438,439
	Decamethylene-4,4′-terephthaloyl-dioxydibenzoate	Single T_g; microscopy; T_m-depression	0–50% II in blend	660,661,662
	Ethylene terephthalate	Single T_g	Semicrystalline	219,220,916
	Hydroxyether of bisphenol-A (Phenoxy)	Single T_g; melt transparent	Semicrystalline	688,689,735
	Vinyl acetate-*co*-vinylidene chloride	Single T_g	II had $\geq 80\%$ vinylidene chloride	36
	Vinyl chloride	Single T_g	Semicrystalline	36,686
	Vinyl chloride, chlorinated	Single T_g	Semicrystalline	36
Caprolactam	Acrylic acid	Single T_g	Semicrystalline	378
	Hexamethylene adipamide	Single T_g; enthalpy recovery kinetics	Semicrystalline	215,830
	Methacrylic acid	SAXS	Semicrystalline	371
	Styrene, sulfonated and Li-neutralized	Single T_g	II had 9.8 mol% sulfonated groups; semicrystalline	583,584
	Styrene, sulfonated and Mn-neutralized	Single T_g; T_m-depression	II had 10.2 mol% sulfonated groups; Semicrystalline	523
	Styrene, sulfonated and Zn-neutralized	Single T_g; T_m-depression	II had 10.1 mol% sulfonated groups; semicrystalline	524
Caprolactone	Acrylonitrile-*co-tert*-butylstyrene	Single T_g; SALS; microscopy	II had 19.8–39.6 wt.% acrylonitrile	1175
	3,3-Bis(chloromethyl)oxetane	Single T_g	Semicrystalline; II was Penton	301,445
	Chlorostyrene	Single T_g	II was *o*-chlorostyrene or mixed *o*- and *p*-isomers; semicrystalline when $\geq 21\%$ I	18,32
	Epichlorohydrin	Single T_g	Semicrystalline	82,223
	Ester	DSC; SALS; X-ray diffraction; microscopy	II was made from terephthaloyl chloride and 4,4′-bis(6-hydroxy-hexyloxy) biphenyl	821
	Ethylene, chlorinated	Single T_g	Semicrystalline when $\leq 90\%$ II; II had $\geq 30\%$ Cl; two T_g's when II had 25% Cl	32,55,191 295
	Hydroxyether of bisphenol-A (Phenoxy)	Single T_g; melt transparent; IGC	Semicrystalline when >50 wt.% I	82,193,332,982
	Nitrocellulose	Single T_g	$\geq 50\%$ I; semicrystalline when $\geq 50\%$ I	82,352,353
	Propylene, chlorinated	Single T_g	I had 66 wt.% Cl; semicrystalline when ≥ 50 wt.% I	18,32
	Vinyl acetate-*co*-vinylidene chloride	Single T_g	II was Saran C (≥ 80 mol% vinylidene chloride); semicrystalline	31,887
	Vinyl bromide	Single T_g	Semicrystalline when $>30\%$ I	147

TABLE 1. *cont'd*

Polymer I of	Polymer II of	Method	Comments	Refs.
	Vinyl chloride	Single T_g; NMR	Semicrystalline when ≥ 30% I	82,352,353,446 628,635,872,900, 1082
	Vinyl chloride, chlorinated	Single T_g	II had 67.2 wt.% Cl; semicrystalline when ≥ 50 wt.% I	54
	Vinyl chloride-*co*-vinylidene chloride	Single T_g	Semicrystalline; II had 79% or 88% vinylidene chloride; some samples of II were Saran B	31,825,868, 873,887
	Vinylidene fluoride	T_m-depression	Semicrystalline	386
	Vinyl methyl ether	Single T_g		1145
Caprolactone-*co*-ethylene terephthalate	Ethylene, chlorinated	Single T_g	I had 33–89 wt.% ethylene terephthalate; II had 67.2 wt.% Cl	525,892
	Hydroxyether of bisphenol-A (Phenoxy)	Single T_g; FTIR	II had 48–82 wt.% ethylene terephthalate	1243
	Vinyl chloride	Single T_g	I had 33 or 44 wt.% ethylene terephthalate	525
	Vinyl chloride, chlorinated	Single T_g	I had 33 wt.% ethylene terephthalate	525
Carbon monoxide-*co*-ethyl acrylate-*co*-ethylene	Vinyl chloride	Single T_g	Semicrystalline when I had >60% ethylene; I had 4.0–19.6% carbon monoxide, 5.5–35.4% ethyl acrylate, and 34.2–79.6% ethylene	692
Carbon monoxide-*co*-2-ethylhexyl acrylate-*co*-ethylene	Vinyl chloride	Single T_g	I had 17.8/34.2/47.9 or 18.6/39.6/41.8 = carbon monoxide/2-ethylhexyl acrylate/ethylene	692
Carbon monoxide-*co*-ethylene-*co*-vinyl acetate	Chlorostyrene	Single T_g	I was Elvaloy 741; II was a mixture of *o*- and *p*- isomers	18
	Propylene, chlorinated	Single T_g	I was Elvaloy 741	18
	Vinyl chloride	Single T_g	Semicrystalline when I had >60% ethylene; I was Elvaloy 741 or 10.5/66.7/22.8 or 10.2/58.2/31.5 = carbon monoxide/ethylene/vinyl acetate	21,40,92
Carbonate of bisphenol-A	Alkylene terephthalate	Single T_g	II had an alkylene group of 2-ethyl-2-methylpropylene, 1,7-heptylene, 1,9-nonylene or 1,5-pentylene (4 blend systems); miscibility arised from *trans*-esterification	1074
	Biphenyl-4,4′ylene sebacate	Single T_g	Up to 40 wt.% II in blend	387
	Butylene adipate	Single T_g	Semicrystalline	174,176
	Butylene terephthalate	Single T_g; FTIR	–	1132
	p-tert-Butylphenol formaldehyde	Single T_g	–	1057
	Caprolactone	Single T_g; SANS; SAXS; FTIR; NMR	Semicrystalline, especially when ≥ 25 wt.% II	174,176,645 948,949,950
	Caprolactone-*co*-ethylene terephthalate	Single T_g; FTIR	II had 48 or 58 wt.% ethylene terephthalate	1120,1242
	Carbonate	Single T_g; transparency	II was carbonate of bisphenol-E, bisphenol-F, bisphenol-Z, bisphenol chloral, dimethylbisphenol-A, dimethylbisphenol-Z, norborane, or tetramethylbisphenol-F (8 miscible blend systems)	427
	Copolyester	Single T_g; melt transparent	Semicrystalline when cast from solvent up to 80 wt.% II; II was prepared from bisphenol-A and 1/1 = terephthalic/isophthalic acid	585
	Copolyester	Single T_g	II was made from terephthalic acid and 1,4-cyclohexane-dimethanol and up to 60 mol% ethylene glycol	23,1093
	Copolyester	Single T_g; melt transparent	Semicrystalline; II was KODAR A150, made from 1,4-cyclohexanedimethanol and 1/4 = isophthalic/terephthalic acid	174,556 581,1251
	Copolyester	Single T_g	II was Hytrel 5556, a multiblock copolymer with poly(tetramethylene ether)glycol terephthalate soft segment	248

TABLE 1. *cont'd*

Polymer I of	Polymer II of	Method	Comments	Refs.
			and tetramethylene terephthalate hard segment	
	1,4-Cyclohexane-dimethylene succinate	Single T_g	Semicrystalline	174,175
	1,4-Cyclohexane-dimethylene terephthalate	Single T_g; melt transparent	Semicrystalline	174,486,581
	Cyclohexyl methacrylate-*co*-methyl methacrylate	Single T_g	II had 6.1–43.8 wt.% cyclohexyl methacrylate	574,622,1039
	Ethylene adipate	Single T_g	Semicrystalline	174,176
	Ethylene succinate	Single T_g	Semicrystalline	174,176
	Ethylene terephthalate	Single T_g	Semicrystalline; ≥50 or 75% II; two T_g's when ≤60% II	337,593 603,1151
	p-(2-Hydroxy-hexafluoroisopropyl) styrene-*co*-styrene	Single T_g; transparency	II had 29–78 mol% styrene; immiscible when II had 83 mol% styrene	571,646, 807
	Maleic anhydride-*co*-styrene	Light scattering	II had 8% maleic anhydride	712
	Methacrylic acid-*co*-styrene	Single T_g	II had 2–23 wt.% methacrylic acid	10,11
	Methyl methacrylate	Single T_g	Blends prepared by precipitation of THF solutions in *n*-heptane or cast from hot THF solutions	29,109, 481,486,715
	Methyl methacrylate-*co*-*p*-methylstyrene	Single T_g	II had ≥70 wt.% methyl methacrylate	357
	Methyl methacrylate-*co*-*N*-phenylmaleimide	Single T_g	II had ≥70 wt.% methyl methacrylate	357
	Methyl methacrylate-*co*-phenyl methacrylate	Single T_g	II had 16–63 wt.% phenyl methacrylate	622
	Methyl methacrylate-*co*-styrene	Single T_g	II had ≤14 wt.% styrene	577,930
	Novolac	Single T_g	II had MW = 1 kg/mol and was made from formaldehyde and 13/17/70 mol% = *p*-*tert*-butylphenyl/*m*-cresol/*o*-cresol	221
	Phenyl methacrylate	Single T_g	–	480,622
	Pyrrole	Single T_g	Blend had 7% II	856
	Vinylidene chloride-*co*-vinyl chloride	Single T_g	II had 13.5 wt.% vinyl chloride; semi-crystalline when ≤25 wt.% I	871
Carbonate of hexafluorobisphenol-A	Alkyl methacrylate	Single T_g; transparency	II had an alkyl group of methyl, ethyl or *n*-propyl (3 miscible blend systems)	225,430
	Isopropyl methacrylate	Single T_g; transparency	≤70 wt.% I in blend	430
	Methyl methacrylate-*co*-α-methylstyrene	Single T_g	II had 81 or 95 wt.% methyl methacrylate	930
Carbonate of tetramethyl-bisphenol-A	Acrylonitrile-*co*-α-methylstyrene	Single T_g	II had 4–16.5 wt.% acrylonitrile	1010
	Acrylonitrile-*co*-styrene	Single T_g; FTIR	II had < 13% acrylonitrile	8,225,1069
	Allyl alcohol-*co*-styrene	Single T_g	II had < 19.1 wt.% allyl alcohol	225
	Butylene sebacate	Single T_g	Semicrystalline	227
	Caprolactone	Single T_g	Semicrystalline	227
	Carbonate of bisphenol-A	Single T_g; transparency; dielectric spectroscopy	–	51,427,1124
	Carbonate	Single T_g; transparency	II was carbonate of bisphenol-AP, bisphenol-E, bisphenol-F, bisphenol-S, bisphenol-Z, bisphenol chloral, dimethylbisphenol-A, dimethylbisphenol-Z, norbonane, tetramethylbisphenol-F or tetramethylbisphenol-P (11 miscible blend systems)	427
	Ester	Single T_g	II was decamethylene decamethylene dicarboxylate, decamethylene sebacate, ethylene adipate, hexamethylene decamethylene dicarboxylate, or hexamethylene sebacate (5 miscible blend systems)	227
	Maleic anhydride-*co*-styrene	Single T_g	II had 8% maleic anhydride	225
	Methyl methacrylate-*co*-styrene	Single T_g	II had < 50 wt.% methyl methacrylate	575,884,1194
	α-Methylstyrene	Single T_g	–	227
	p-Methylstyrene-*co*-tetrahydro-furfuryl methacrylate	Single T_g	II had ≤50 mol% tetrahydrofurfuryl methacrylate	270

TABLE 1. *cont'd*

Polymer I of	Polymer II of	Method	Comments	Refs.
	Styrene-*co*-tetrahydrofurfuryl methacrylate	Single T_g	II had ≤53 mol% tetrahydrofurfuryl methacrylate	270
Cellulose	Acrylonitrile	NMR; single T_g; microscopy; WAXD	–	560,627,1208 556
	Caprolactone	NMR	–	625,1075
	Ethylene glycol	Single T_g; FTIR	–	
	Vinyl acetate	Single T_g	≥70% I in blend	626
	Vinyl alcohol	NMR; FTIR; T_m-depression	–	560,623,744,1075
	4-Vinylpyridine	Single T_g, NMR	–	559,1208
Cellulose acetate	2,6-Dimethyl-1,4-phenylene ether, phosphonate derivative	Single T_g	II had 9.5% P	87
	2,6-Dimethyl-3-bromo-1,4-phenylene ether, phosphonate derivative	Single T_g	II had 10.5% P	87
	Styrene, phosphonate derivative	Single T_g	II had 8.0% P	87
	Styrene, phosphorylated	Single T_g	II had more than 1 phosphoryl group per 4 styrene units	550
	Styrenephosphonate ester	Single T_g	Blend initially prepared was heterogeneous, became miscible when annealed above T_g	792
	styrene-*co*-vinylidene chloride phosphonylated, chloromethylated	Single T_g; electron microscopy	I was Eastman 394–45; II had 7% P, 14.5% Cl	88
	styrene-*co*-inylidene chloride phosphonylated	Single T_g	II had 8.6% P	87
	4-Vinylpyridine	Single T_g; cast films transparent	Semicrystalline; I had 39.4% acetyl content or had 10H/2 glucose	27,86
Cellulose acetate-butyrate	Ethylene-*co*-vinyl acetate	Single T_g; transparent films	I had 18.5/45 = acetic acid/butyric acid and II had 80% vinyl acetate; two T_g's when II had 70% vinyl acetate	93,452
	Hydroxybutyrate-*co*-valerate	Single T_g; WAXD; NMR	II had 10 mol% valerate; miscible when blend had 20–50% II, and partially miscible when blend had 60–80% II	84
Cellulose acetate propionate	Alkylene glutarate	Single T_g	The alkylene group was ethylene, diethylene, hexamethylene, pentamethylene, tetramethylene or trimethylene (6 miscible blend systems)	927
Cellulose triacetate	Highly subsitituted cyanoethyl cellulose	Single T_g; FTIR; microscopy	–	1026
Chitin	*N*-Vinylpyrrolidone	Single T_g; FTIR	–	1133
Chitin-*g*-2-methyl-2-oxazoline	Vinyl alcohol	Single T_g; FTIR	–	913
	Vinyl chloride	Sinlge T_g; FTIR	Blend had ≤10 wt.% II	914
Chitosan	Ethylene oxide	T_m depression	–	1245
Chitosan acetate	Ethylene oxide	FTIR; microscopy	–	1227
p-Chloro-(3-ethenoxypropyl) cinnamate	*p*-Methoxy-(6-ethenoxyhexyl) cinnamate	Single T_g	–	515
	p-Methoxy-(6-ethenoxypropyl) cinnamate	Single T_g	–	515
	p-Methyl-(3-ethenoxypropyl) cinnamate	Single T_g	–	515
1-Chloroethyl methacrylate	Alkyl methacrylate	Single T_g; transparency	The alkyl group of II was methyl, ethyl, *n*-propyl, isopropyl, *n*-butyl or tetrahydrofurfuryl (6 miscible blend systems)	1152
	Ester	Single T_g; transparent melt	II was butylene adipate, caprolactone, 2,2-dimethyl-1,3-propylene adipate, 2,2-dimethyl-1,3-propylene sebacate, 2,2-dimethyl-1,3-propylene succinate or hexamethylene sebacate (6 miscible blend systems)	1154
2-Chloroethyl methacrylate	Alkyl methacrylate	Single T_g; transparency	The alkyl group of II was methyl, ethyl or tetrahydrofurfuryl (3 miscible blend systems)	612
	Ester	Single T_g; transparent melt	II was butylene adipate, caprolactone, 2,2-dimethyl-1,3-propylene adipate, 2,2-dimethyl-1,3-propylene sebacate, ethylene adipate or hexamethylene sebacate (6 miscible blend systems)	609,611
	N-vinylpyrrolidone	Single T_g	–	607

TABLE 1. *cont'd*

Polymer I of	Polymer II of	Method	Comments	Refs.
Chloromethyl methacrylate	Alkyl methacrylate	Single T_g	II had an alkyl group of methyl, ethyl, *n*-propyl, isopropyl, acetonyl or tetrahydrofurfuryl (6 miscible blend systems)	123,273
	Carbonate of bisphenol-A	Single T_g	Miscibility depended on method of preparation	271
	Ester	Single T_g; transparent melt	II was butylene adipate, caprolactone, 2,2-dimethyl-1,3-propylene adipate, 2,2-dimethyl-1,3-propylene sebacate, 2,2-dimethyl-1,3-propylene succinate, ethylene adipate, ethylene succinate or hexamethylene sebacate (8 miscible blend systems)	609,611
	N-vinylpyrrolidone	Single T_g	–	607
Chloroprene	Ethylene-*co*-methyl acrylate	Single T_g; phase contrast microscopy	Semicrystalline	396
	Isoprene, epoxidized	Single T_g; FTIR		597
3-Chloropropyl methacrylate	Acrylonitrile-*co*-*p*-methylstyrene	Single T_g	II had 15–33 wt.% AN	1105
	Acrylonitrile-*co*-styrene	Single T_g	II had 12–35 wt.% AN	1105
	Ester	Single T_g	II was butylene adipate, caprolactone, 2,2-dimethyl-1,3-propylene adipate or hexamethylene sebacate (4 miscible blend systems)	1111
	Tetrahydrofurfuryl methacrylate	Single T_g	–	1104
o-Chlorostyrene	Styrene	Single T_g	–	396
o-Chlorostyrene-*co*-*p*-chlorostyrene	2,6-Dimethyl-1,4-phenylene ether	Single T_g; transparency	I had 23-64% *p*-chlorostyrene	16
	Styrene	Single T_g	After quenching from 145°C; I had 71–92 mol% *o*-chlorostyrene; two T_g's when I had ≤ 62 mol% *o*-chlorostyrene	131,803
o-Chlorostyrene-*co*-*o*-fluorostyrene	2,6-Dimethyl-1,4-phenylene ether	Single T_g; transparency; NMR	I had 14–40 mol% *o*-chlorostyrene; two T_g's when I had >36 mol% *o*-chlorostyrene	22,840, 843
p-Chlorostyrene-*co*-*o*-fluorostyrene	2,6-Dimethyl-1,4-phenylene ether	Single T_g; transparency; NMR	I had 13–74 mol% *p*-chlorostyrene; two T_g's when I had >74 mol% *p*-chlorostyrene	22,840, 843
p-Chlorostyrene-*co*-styrene	2,6-Dimethyl-1,4-phenylene ether	Single T_g	I had ≥ 34.7 mol% styrene; two T_g's when I had <34.7 mol% styrene	243,413, 749
Collagen hydrolyzate	Ethyl acrylate	Single T_g	–	578
Copolyester	Hydroxyether of bisphenol-A (Phenoxy)	Single T_g	I was cyclohexylene dimethylene tere/isophthalate	689
	p-(2-Hydroxy-hexafluoroisopropyl) styrene-*co*-styrene	Single T_g; clear films	I was KODAR PETG (made from terephthalic and isophthalic acid and ethylene glycol and 1,4-dihydroxymethyl cyclohexane; II had 60 mol% styrene; immiscible when II had ≥ 83 mol% styrene	571,646
		Single T_g; clear films	I was VITEL PE-307; II had 83–90.3 mol% styrene	646
		Single T_g	I was VITEL VPE-5545; II had 83 mol% styrene; immiscible when II had 90.3 mol% styrene	646
	Vinyl chloride	Single T_g for II with soft segments of I	I was Hytrel, a multiblock copolymer with poly(tetramethylene ether) glycol terephthalate soft segments and tetramethylene terephthalate hard segments; hard segments crystalline; two T_g's after 130°C annealing; Refs. 343, 344 showed single T_g to 50 or 60 wt.% I	343,344, 617
	Vinyl chloride	Single T_g	I was made from adipic acid, hexane-1,6-diol and neopentanediol and had $M_n = 2$ kg/mol	331
Copolyester-carbonate	Ethylene terephthalate	Single T_g	I was from $1/2 =$ terephthalate/ bisphenol-A with ester and carbonate linkages	3

TABLE 1. *cont'd*

Polymer I of	Polymer II of	Method	Comments	Refs.
	Vinyl chloride	Single T_g	I was made from adipic acid and hexane-1,6-diol and neopentane-diol and diphenyl carbonate	333
Copolyether-amide	*N*-vinylpyrrolidone	Single T_g; transparency	Studied up to 30% II; I was made from isophthaloyl chloride and *cis*-4,4′-diamino-dibenzo-18-crown-6	720
Copolymer of bromohydro-quinone and 4,4′-(decame-thylenedioxy) bibenzoic acid	Copolymer of *p*-hydroxybenzoic acid and 3-methyl-1,6-hexanediol-terephthalic acid	Single T_g; microscopy	Transition temperature from a mesophase to an isotopic phase changed continously and smoothly depending on the composition	380
	Copolymer of 4,4′-(decamethylene-dioxy)-bibenzoic acid and 4,4′-(ethylenedioxy)diphenol	Single T_g; microscopy	Transition temperature from a mesophase to an isotopic phase changed continously and smoothly depending on the composition	380
2-Cyanoethyl methacrylate	Alkyl methacrylate	Single T_g	II had an alkyl group of methyl, acetonyl or tetrahydrofurfuryl (3 miscible blend system)	1234
	2-Ethyl-2-oxazoline	Single T_g	Blend had ≥ 80 wt.% I	1236
	2-Hydroxyethyl methacrylate	Single T_g; FTIR	-	1235
	2-Hydroxypropyl methacrylate	Single T_g; FTIR	Blend had ≤ 50 wt.% I	1235
	Tertiary amide	Single T_g	II was *N,N*-dimethylacrylamide, *N*-methyl-*N*-vinylacetamide or *N*-vinyl-2-pyrrolidone (3 blend systems); formed complexes	1236
Cyanomethyl methacrylate	Alkyl methacrylate	Single T_g; FTIR	II had an alkyl group of acetonyl, 2-hydroxyethyl or 2-hydroxypropyl (3 miscible blend systems)	1233, 1235
	2-Ethyl-2-oxazoline	Single T_g	Blend had ≥ 60 wt.% I	1236
	Tertiary amide	Single T_g	Complexation formation; II was *N*-vinylpyrrolidone, *N,N*-dimethyl-acrylamide or *N*-methyl-*N*-vinylacet-amide (3 miscible blend system)	1236
1,4-Cyclohexanedimethylene succinate	Epichlorohydrin	Single T_g	Semicrystalline	223
	Hydroxyether of bisphenol-A (Phenoxy)	Single T_g; transparent melt	Semicrystalline ≥ 50 wt.% I	332
	Vinyl chloride-*co*-vinylidene chloride	Transparent melt; large T_m-depression	II was Saran (86.5% vinylidene chloride)	868
	Vinyl chloride	Single T_g	Semicrystalline ≤ 30 wt.% II	898
1,4-Cyclohexanedimethylene 1,4-Cyclohexanedicarboxylate	Arylate	Single T_g; PALS	II was Ardel D100	1251
	Carbonate of bisphenol-A	Single T_g' PALS	II was Ardel D100	1251
Cyclohexyl methacrylate	Vinyl chloride	Single T_g; NMR	-	641
	Vinyl chloride-*co*-vinylidene chloride	Single T_g	Semicrystalline ≥ 75% II; II had 86.5 wt.% vinylidene chloride	409,870
	2-Vinylnaphthalene	Single T_g; excimer fluorescence	I had low MW; II had MW = 70 kg/mol	231
Decamethylene decamethylene dicarboxylate	Vinyl chloride	Single T_g	Semicrystalline	872
Decamethylene sebacate	Epichlorohydrin	Single T_g	Semicrystalline	223
Dianhydrosorbityl dicarboxylate	Dianhydrosorbityl dicarboxylate	Single T_g; microscopy	6 Miscible blend systems based on different polyesters; the dicarboxylate was adipate, oxalate, sebacate, suberate or succinate	925
2,3-Dichloro-1-propyl acrylate	Ethyl acrylate-*co*-glycidyl methacrylate	Single T_g	II had 65% ethyl acrylate	181
2,2-Dichloroethyl methacrylate	Alkyl methacrylate	Single T_g; transparency	The alkyl group of II was methyl, ethyl, *n*-propyl, isopropyl, *n*-butyl, isoamyl, cyclohexyl or tetrahydrofurfuryl (8 miscible blend systems)	1110
2,6-Diethyl-1,4-phenylene ether	Styrene	Single T_g	-	134
N,N-dimethylacrylamide	Allyl alcohol-*co*-styrene	Single T_g; FTIR	Formed complexes; II had 4.5 or 6.5 wt.% OH groups	974
	Alkyl methacrylate	Single T_g; FTIR	II had an alkyl of chloromethyl, 2-chloroethyl, 3-chloropropyl,	1108

TABLE 1. *cont'd*

Polymer I of	Polymer II of	Method	Comments	Refs.
			2-bromoethyl or 2-iodoethyl (5 miscible blend systems)	
	Vinylidene fluoride	Single T_g	Semicrystalline $\geq$60 wt.% II	241
N,N-Dimethylacrylamide-*co*-ethylene	Vinyl chloride	Single T_g	I had 71.4 or 73.1 wt.% ethylene; two T_g's when I had $\geq$75.1 wt.% ethylene	563
2,6-Dimethyl-1,4-phenylene ether	Acrylic acid-*co*-styrene	Single T_g	II had 4.7–8.5 wt.% acrylic acid	921,1022
	p-Bromostyrene-*co*-fluorostyrene	Single T_g; FTIR	II had 11–73 mol% *p*-bromostyrene	547,834
	Cyclohexylmaleimide-*co*-styrene	Light scattering	I had 83 wt.% styrene	712
	o-Fluorostyrene-*co*-*p*-fluorostyrene	Single T_g; transparency	II had 10–38% *para* isomer; two T_g's when II had 5 or $\geq$43% *para* isomer	412,835
	o-Fluorostyrene-*co*-styrene	Single T_g; transparency	II had $\geq$9 mol% styrene	836,839,842
	p-Fluorostyrene-*co*-styrene	Single T_g; transparency	II had $\geq$44 mol% styrene	531,532,836,839,842
	p-(2-Hydroxy-hexafluoroisopropyl) styrene-*co*-styrene	Single T_g	II had 77.9–90.3 mol% styrene	571,572,646,807
	Luoloylmeleimide-*co*-styrene	Light scattering	II had 81 wt.% styrene	712
	Maleic anhydride-*co*-styrene	Single T_g; transparency; microscopy	II had 5.9–12.5 wt.% maleic anhydride	232,233, 1022,1026
	Methacrylic acid-*co*-styrene	Single T_g	II had 5.9 or 7.8 mol% methacrylic acid	917,921
	2-Methyl-6-benzyl-1,4-phenylene ether	Single T_g; transparency	–	751
	Methyl methacrylate-*co*-styrene	Single T_g	II had 2–20 wt.% methyl methacrylate	258,461,1022
	2-Methyl-6-phenyl-1,4-phenylene ether	Single T_g	–	752,753
	α-Methylstyrene	Single T_g	–	134,459,691
	α-Methylstyrene-*co*-styrene	Single T_g	All compositions of II	459,754
	o-Methylstyrene	NMR	NMR showed heterogeneity on a 3-nm scale	195
	p-Methylstyrene	Single T_g	–	195,235,788
	p-Nitrostyrene-*co*-styrene	Single T_g	II had <22 mol% nitrostyrene	155,158
	N-phenylmaleimide-*co*-styrene	Single T_g; light scattering	II had 84 or 90 wt.% styrene	712,1102
	Styrene	Single T_g; transparency; NMR	–	39,201,526,589,663, 750,753,784,1207
	Styrene, head-to-head	Single T_g	–	463
	Styrene, iodinated	Single T_g	II had $\leq$47% iodination	261
	Styrene, sulfonated and metal-neutralized	Single T_g	II had up to 7.8 mol% sulfonation (Ref. 677); II had 2.8 mol% sulfonation and was neutralized by Na, Zn, Ni or Mn, and miscible when blend had $\leq$40 wt.% I (Ref. 1200)	677, 1200
	Styrene, syndiotactic	Single T_g	–	954
	Styrene-*b*-isoprene-*b*-styrene	Single T_g for mixed with styrene blocks of II	II had block MW 15-51-17 and 78-52-80 kg/mol	568
	Styrene-*co*-2,2,6,6-tetramethyl-piperidinyl methacrylate	Single T_g	II had $\leq$24 wt.% 2,2,6,6-tetramethylpiperi-dinyl methacrylate	257
	Urethane acrylate	Single T_g; FTIR	I and II formed interpenetrating network	567
2,6-Dimethyl-1,4-phenylene ether, carboxylated	Styrene	Single T_g	11.8 mol% of repeat units in I carboxy-lated; two T_g's when 35.0 mol% repeat units in I carboxylated	874
2,6-Dimethyl-1,4-phenylene ether, brominated phosphonylated	Cellulose acetate	Single T_g; electron microscopy	II was Eastman 394–45	88
2,6-Dimethyl-1,4-phenylene ether, modified	Epichlorohydrin, modified	Single T_g	Both I and II had at least 25% carbazolyl or 3,5-dinitrobenzoyl groups	664
2,6-Dimethyl-1,4-phenylene ether, sulfonylated	Acrylonitrile-*co*-styrene	Single T_g	I had 20–26 wt.% sulfonylation	410
	p-Bromostyrene	Single T_g	I had >12 mol% sulfonylation	1216,1220
	o-Bromostyrene-*co*-*p*-bromostyrene	Single T_g	High *p*-bromostyrene content and high degree of sulfonylation favored miscibility	1216
	p-Chlorostyrene	Single T_g	II had >9 mol% sulfonylation	1217,1220
	o-Chlorostyrene-*co*-*p*-chlorostyrene	Single T_g	Miscibility depended on compositions of I and II	1217
	o-Chlorostyrene-*co*-*o*-fluorostyrene	Single T_g	Miscibility depended on compositions of I and II	1218

TABLE 1. *cont'd*

Polymer I of	Polymer II of	Method	Comments	Refs.
	p-Chlorostyrene-*co*-*o*-fluorostyrene	Single T_g	Miscibility depended on compositions of I and II	1218
	o-Fluorostyrene	Single T_g	I had 4–17 mol% sulfonylation	1220
	p-Fluorostyrene	Single T_g	I had 17–66 mol% sulfonylation	1220
	o-Fluorostyrene-*co*-*p*-fluorostyrene	Single T_g	Miscibility depended on compositions of I and II	1215
	p-Fluorostyrene-*co*-styrene	Single T_g	I had 20–26 wt.% sulfonylation	410
	Phenylvinyl *sec*-butyl ether-*alt*-*N*-phenylmaleimide	Single T_g	I had 68–87 mol% sulfonylation	1219
	Phenylvinyl ethyl ether-*alt*-*N*-phenylmaleimide	Single T_g	I had 61–91 mol% sulfonylation	1219
	Styrene	Single T_g	I had <31 wt.% sulfonylation	410
α,α-Dimethyl-β-propiolactone (pivalolactone)	Vinyl chloride	T_m-depression	Semicrystalline	32,33
Dimethylsiloxane	Ethylene-*co*-methyl acrylate	Single T_g; FTIR	I had a small amount of vinyl groups; II had 21 wt.% methyl acrylate	1182
Dimethylsiloxane, modified	Butyl methacrylate	Single T_g; FTIR	One of the methyl groups in the repeating unit of I was changed to 4-hydroxy-4,4-bis (trifluoromethyl) butyl group	127
	Ethylene glycol	Single T_g; FTIR	One of the methyl groups in the repeating unit of I was changed to 4-hydroxy-4,4-bis(trifluoromethyl) butyl group	127
2,6-Dipropyl-1,4-phenylene ether	Styrene	Single T_g	–	134
Dodecamethylene adipamide, *N,N*-dimethyl substituted	*p*-(2-Hydroxy-hexafluoroisopropyl) styrene-*co*-styrene	Single T_g	Semicrystalline when $\leq 50\%$ substitution on I	454
Dodecamethylene adipate	Epichlorohydrin	Single T_g	Semicrystalline	223
	Vinyl chloride	Single T_g	Semicrystalline	872
Dodecamethylene decamethylene dicarboxylate	Vinyl chloride	Single T_g	Semicrystalline	872
Dodecamethylene dodeca-methylene dicarboxylate	Vinyl chloride	Single T_g	Semicrystalline	872
Enaminonitrile	Ethylene glycol	Single T_g	–	587
	Tertiary amide	Single T_g	II was *N,N*-dimethylacrylamide, 2-ethyl-2-oxazoline or *N*-vinyl-2-pyrrolidone (3 miscible blend systems)	587
	4-Vinylpyridine	Single T_g	–	587
Epichlorohydrin	Acrylonitrile-*co*-styrene	Single T_g	II had 18 or 25 wt.% acrylonitrile	305
	Alkyl acrylate	Single T_g	II had an alkyl group of ethyl or *n*-propyl (2 miscible blend systems)	224,226
	Alkyl methacrylate	Single T_g	II had an alkyl group of ethyl, *n*-propyl, *n*-butyl or cyclohexyl (4 miscible blend systems)	224
	Butyl acrylate rubber	Single T_g	II was Hycar 4043	226
	Ethyl acrylate rubber	Single T_g	II was Hycar 4051EP	226
	Ester	Single T_g	II was ethylene adipate, ethylene sebacate or 2,2-dimethyl-1,3-propylene adipate (3 miscible blend systems)	223,278
	Glycidyl methacrylate	Single T_g	–	864
	Glycidyl methacrylate-*co*-methyl methacrylate	Single T_g	II had 76% glycidyl methacrylate	864
	Hexamethylene sebacate	Single T_g	–	864
	Methacrylonitrile-*co*-methyl methacrylate	Single T_g	II had 30–40 mol% methacrylonitrile	864
	Methyl methacrylate	Single T_g	Broad T_g might due to separate phases with differing T_g's within the mixture	135,224
	Vinyl acetate	Single T_g	–	303
Epichlorohydrin-*co*-ethylene glycol	Neopentyl glycol adipate	Transparency	I was Hydrin 200; refractive indices not equal in the temperature range investigated	288
Ester	Ester	Single T_g; microscopy	13 Miscible blend systems based on different linear aliphatic polyesters	925
	Ester	Melting behavior	Both polymers I and II were liquid crystalline; II had one more ethylene unit in the main chain	979

TABLE 1. *cont'd*

Polymer I of	Polymer II of	Method	Comments	Refs.
Ester, hyperbranched and 3,5-dihydroxyphenyl-terminated	Aramide	Single T_g	II was Trogamid T or MXD-6	1125
	Amide	Single T_g	II was nylon-6	1125
	Butylene adipate	Single T_g	–	1125
	Copolyester	Single T_g	II was made from terephthalic acid and a mixture of ethylene glycol and 1,4-cyclohexane dimethanol	965
Ester, hyperbranched and 3,5-diacetoxyphenyl-terminated	Butylene terephthalate	Single T_g	–	1125
	Copolyester	Single T_g	II was made from terephthalic acid and a mixture of ethylene glycol and 1,4-cyclohexane dimethanol	1125
Ether ether ketone	Arylketone	Single T_g	II had 25, 50 or 57% ketone content	333
	Etherketone	Single T_g	I was oxy-1,4-phenyleneoxy-1,4-phenylenecarbonyl-1,4-phenylene; II was oxy-1,4-phenylenecarbonyl-1,4-phenylene; semicrystalline	739
	Etherimide	Single T_g; microscopy; WAXD; T_m-depression	I was Victrex 450G; II was Ultem 1000; semicrystalline	172,946,1037 1178
	Ether sulfone	Single T_g	–	883
Ether ether ketone, sulfamidated	Amideimide	Single T_g; FTIR	I had degree of sulfamidation of 1.33; II was Torlon 4000T	1061
Ether ether ketone, sulfonated	Amideimide	Single T_g; FTIR	I had degree of sulfonation of 0.42, 0.53 or 1.00; II was Torlon 4000T	414,1061
	Etherimide	Single T_g; FTIR	II was Ultem 1000	414,1061
Ether ether sulfone, phenolphthalein	Epoxy	Single T_g; microscopy	Miscible when II was cured by amine; immiscible when II was cured by anhydride	1023
Etherimide	Amideimide	Single T_g	I was Ultem 10000; II was Torlon 4203L	1147
	Ethylene terephthalate	Single T_g; microscopy; T_m-depression	I was Ultem 1000	942,1054,1127
	Imide	Single T_g	I was Ultem 1000; II was based on diphenylpyromellitic dianhydride (DPPMDA) (3 different imides)	240
Etherimide ether	Thioetherimide ether	NMR	I was made from 4,4′-oxydianiline (ODA) and 4,4′-(1,4-phenylene-dioxy)diphthalic acid; II was made from ODA and 4,4′-thio-diphthalic anhydride	1000
Ether ketone ketone	Etherimide	T_m-depression	II was Ultem 1000	946
Ether sulfone	Aramid	Single T_g	II was made from isophthaloyl chloride and bis(4-aminophenyl) ether	562,600
	Imide	Single T_g; NMR	II was Polyimide XU218	372
	Imide	Single T_g	II was Matrimide 5218	510,940
	N,N′-(oxydi-*p*-phenylene) isophthalamide	Single T_g	–	1031
	Phenylene ether ether ketone	Single T_g	–	1184
	Phenylene ether sulfone ketone	Single T_g	–	1184
	Phenylene sulfone ether sulfone ketone	Single T_g	–	1184
	Phenylene thioether ether ether ketone	Single T_g	–	1184
	m-Phenylene isophthalamide	Single T_g	Prepared by *in situ* blending	1030
Ether urethane	Vinyl chloride	Single T_g	20 or 40 wt.% II; I was Adiprene L-100 and 4,4′-methylene-bis-2-chloroaniline	344
3-Ethenoxypropyl cinnamate	*p*-Methyl-(3-ethenoxypropyl) cinnamate	Single T_g	–	515
Ethyl acrylate	Novolac	Single T_g	II had MW about 1 kg/mol; II was formaldehyde and 13/17/70 mol% = *p*-*tert*-butylphenol/*m*-cresol/*o*-cresol or formaldehyde and 15/17/68 mol% = 2-*tert*-butylphenol/*m*-cresol/*o*-cresol	221

TABLE 1. *cont'd*

Polymer I of	Polymer II of	Method	Comments	Refs.
	Hexafluoroacetone-*co*-vinylidene fluoride	Single T_g	II had 8 mol% vinylidene fluoride	411,1059
	Styrene, sulfonated	Single T_g; FTIR	II had 7.2 mol% sulfonated units	1198
	Styrene-*co*-*p*-vinylphenol	Single T_g; FTIR	II had >4.46 mol% vinylphenol	1198
	Vinyl chloride	Single T_g	*In situ* polymerized II; other mixtures formed two phases (Refs. 296, 426 for example)	846
	Vinyl chloride-*co*-vinylidene chloride	Single T_g; transparency	II was Saran ($\geq$80% vinylidene chloride); I had MW = 50 kg/mol; two T_g's when I had MW = 140 kg/mol and II was Saran (86.5 wt.% vinylidene chloride)	812,870
	Vinylidene fluoride	Single T_g; transparency	Semicrystalline $\geq$25 wt.% II	56,80,844
Ethyl acrylate-*co*-methacrylonitrile-*co*-α-methylstyrene	Vinyl chloride	Single T_g; transparency	I had 2/40/58 = ethyl acrylate/methacrylonitrile/α-methylstyrene or unknown composition	422,424
Ethyl acrylate-*co*-methyl methacrylate	Vinyl chloride	Single T_g; electron microscopy	I was Polaroid K120N (95% methyl methacrylate)	886
Ethyl acrylate-*co*-4-vinylpyridine	Styrene-*co*-styrene sulfonic acid	Single T_g; transparency	I and II both $\geq$5% of second monomer (data obtained $\leq$10% substitution)	210,773
	Vinyl chloride	Single T_g	I had 2–14 mol% 4-vinylpyridine	137
	Vinyl chloride, sulfonated	Single T_g	I had 6.2 mol% 4-vinylpyridine; II had 3.7 mol% sulfonic acid	137
(*N*-ethylcarbozol-3-yl)methyl acrylate	2-(3,5-Dinitrobenzoyl) oxyethyl methacrylate	Single T_g; NMR	–	760
(*N*-ethylcarbozol-3-yl)methyl methacrylate	2-(3,5-Dinitrobenzoyl) oxyethyl methacrylate	Single T_g; NMR	–	761
Ethyl methacrylate	Novolac	Single T_g; FTIR	II had MW about 1 kg/mol and was formaldehyde and 13/17/70 mol% = *p*-*tert*-butylphenol/*m*-cresol/*o*-cresol	221,434
	Ethyl acrylate	Single T_g	–	156
	p-(2-Hydroxy-hexafluoro-isopropyl)styrene-*co*-styrene	Single T_g; transparency	II had 90.3–98.9 mol% styrene	103,571,646
	Vinyl acetate	Transparency	Transparent film when I <25 wt.% or when content of I toward 100 wt.%	634
	Vinyl chloride	Single T_g; transparency	–	234,319,649, 812,846
	Vinyl chloride-*co*-vinylidene chloride	Single T_g; transparency	II was Saran ($\geq$80% vinylidene chloride) or 86.5 wt.% vinylidene chloride; semicrystalline $\leq$30% I	409,812, 870
	Vinylidene fluoride	Single T_g	Semicrystalline when $\geq$40% II; two T_g's when >60% II	244,361,476 630,695
Ethylene, chlorinated	Acrylonitrile-*co*-butadiene	Single T_g	Depended on Cl content and acrylonitrile content	96,161
	Hexamethylene terephthalate	Single T_g	I had 48% Cl; immiscible with I had 36% Cl	36
	Methyl methacrylate	Single T_g; transparency; electron microscopy	I had $\geq$50 wt.% Cl; II was atactic, isotactic or syndiotactic (Ref. 1204)	99,296,812 848,1204
	Neopentyl glycol adipate	Single T_g	I had 42 or 48 wt.% Cl; immiscible when I had $\leq$36 wt.% Cl	288
	Vinyl chloride, chlorinated	Single T_g	I and II with identical chlorine content were immiscible	818
Ethylene, chlorosulfonated	Vinyl chloride	Single T_g	I had 1% S as SO_2Cl and 42 wt.% Cl; stated immiscible when I had 30 wt.% Cl in Ref. 296	200
Ethylene adipate	Hydroxyether of bisphenol-A (Phenoxy)	Single T_g; transparent melt	Semicrystalline when $\geq$50 wt.% I	332
Ethylene-*co*-methacrylic acid	Ethylene glycol	FTIR	I had 55 wt.% methacrylic acid	287
	Ethylene glycol-*co*-propylene glycol	Single T_g; FTIR	I had 18, 32, 44 or 55 wt.% methacrylic acid; II had 70 wt.% ethylene oxide	494
	2-Ethyl-2-oxazoline	FTIR	I had 44 wt.% methacrylic acid	512
	Styrene-*co*-2-vinylpyridine	FTIR	I had 32 wt.% methacrylic acid; II had 70 wt.% 2-vinylpyridine	495

TABLE 1. *cont'd*

Polymer I of	Polymer II of	Method	Comments	Refs.
	Tetramethylene glycol	FTIR	I had 55 wt.% methacrylic acid	496
	Vinyl ethyl ether	FTIR	I had 55 wt.% methacrylic acid	496
	Vinyl methyl ether	Single T_g; FTIR	I had 18, 32, 44 or 55 wt.% methacrylic acid	494
	2-Vinylpyridine	FTIR	Miscible when I had 18 wt.% methacrylic acid and formed complexes when I had 44 or 55 wt.% methacrylic acid; formed complexes when I had 32 wt.% methacrylic acid and was $\leq 35\%$ I in blend	494
Ethylene-*co*-methacrylic acid, zinc neutralized	Vinyl methyl ether	FTIR	I had 44 wt.% methacrylic acid	732
	4-Vinylpyridine	NMR	I had 15 wt.% methacrylic acid and 60% zinc-neutralized	52
Ethylene-*co*-methyl acrylate *co*-unspecified acid	Vinyl chloride	Single T_g	I was Vamac N-123	395
Ethylene orthophthalate	Vinyl acetate	Single T_g	–	829
Ethylene glycol	Copolyester-polyurethane	Single T_g	–	363
	Epoxy resin	Single T_g	Miscible when II was uncured; immiscible when II was cured (Ref. 313)	313, 1118,1119
	Ethersulfone	Single T_g; light scattering	–	317,534,743
	Ethyl methacrylate	Single T_g	–	130
	Ethylene-*co*-vinyl acetate	Single T_g	II had 87.1 wt.% vinyl acetate (Ref. 132); II had 73.4 wt.% vinyl acetate, miscible with I of $M_w = 20$ and 100 kg/mol (Ref. 328)	132, 328
	Hydroxyether of bisphenol-A (Phenoxy)	Single T_g; NMR	Semicrystalline when >40% I	363,364,690
	p-(2-Hydroxy-hexafluoroisopropyl) styrene-*co*-styrene	Single T_g	II had 77.9 mol% styrene and I/II was 1/8-1/2; semicrystalline and no amorphous phase	806
	Methacrylic acid	Single T_g; NMR	Formed complexes in water and dimethylsulfoxide	374,1128
	Methacrylic acid-*co*-styrene, Na-neutralized	FTIR	I had 5.6–17.9 mol% acid	1098
	Methyl methacrylate	Single T_g; FTIR; NMR	I was miscible with atactic or syndiotactic II and immiscible with isotatic II; semicrystalline when >20 wt.% I	124,389,511 552,759, 1192
	Resorcinol	NMR	–	51
	Styrene, sulfonated and Na-neutralized	Single T_g	II had 2.9–8.8 mol% sulfonation; miscible when blend had low I content	498
	Styrene-*co*-*p*-vinylphenol	Single T_g	II had 13.1 mol% styrene and I/II was 1/8–1/1; semicrystalline at higher I content and no amorphous phase miscibility	806
	Styrene-*co*-vinylphenol trifluoromethyl carbinol	Single T_g	II had 84.4 mol% styrene and I/II was 1/8–1/4 or II had 54.5 mol% styrene and I/II was 1/8–1/2; semicrystalline at higher I content and no amorphous phase miscibility	806
	Sulfone	Transparency; light scattering	I had $M_n = 3.5$– 4.0 kg/mol; immiscible when I had $M_n = 200$ kg/mol	796
	Vinyl acetate	Single T_g	Ref. 397 stated miscible when ≥ 40 wt.% II in blend; Ref. 311 stated completely miscible if I had $M_w = 20$ kg/mol, and miscible up to 50 wt.% II if I had $M_w = 100$ kg/mol	311,397, 553
	Vinyl chloride	Single T_g; T_m-depression; NMR; IGC	Semicrystalline	418,1126,994
	Vinylnapthalene	Single T_g	Semicrystalline when >50% I; two amorphous phases when 25–50% I	178,580,679
	p-Vinylphenol	FTIR; NMR; X-ray diffraction	Semicrystalline	668,888,1150, 1149
Ethylene-*co*-sulfur dioxide-*co*-vinyl acetate	Vinyl chloride	Single T_g; transparency	I had 72.7/8.8/18.5 = ethylene/sulfur dioxide/vinyl acetate; immiscible when	339

TABLE 1. *cont'd*

Polymer I of	Polymer II of	Method	Comments	Refs.
			I had 89.0/3.2/7.8 = ethylene/sulfur dioxide/vinyl acetate	
Ethylene terephthalate	Hydroxyether of bisphenol-A (Phenoxy)	Single T_g	T_g's of I and II were close; semi-crystalline	689
	Liquid crystalline copolyester	Single T_g	II was copolymer of ethylene terephthalate (40%) and hydroxybenzoic acid (60%) (Ref. 898) or a segmental block copolyester (Ref. 1099)	898, 1099
	Ethylene-2,6-naphthalene dicarboxylate	Single T_g	Miscibility arised from *trans*-esterification	912
Ethylene-*co*-vinyl acetate	Acrylic acid-*co*-alkyl acrylate	Single T_g	II had an alkyl group of *n*-butyl, ethyl, ethylhexyl or methyl (4 blend systems); miscibility depended on compositions of I and II	924
	3-Alkyl thiophene	Microscopy	I had 20 wt.% of vinyl acetate; II had an alkyl group of dodecyl or octyl; blend had < 30 wt.% II	1033,1095
	Aniline, *N*-octadecylated	Microscopy	I had 20 wt.% vinyl acetate; II was 60.2 mol% alkylated	1246
	Chloroprene	Single T_g; microscopy	I had 28 wt.% vinyl acetate	1081
	Hexafluoroacetone-*co*-vinylidene fluoride	Single T_g	I had ≥ 70% vinyl acetate; II had 8.9 mol% hexafluoroacetone	336
	Novolac	Single T_g; FTIR	I had 14–50 wt.% vinyl acetate	1130
	Propylene, chlorinated	Single T_g	I had 40, 44.3 or 45 wt.% vinyl acetate; II had 40 or 50 wt.% Cl	499,500
	Vinyl chloride	Single T_g	I had 65–75 wt.% vinyl acetate; two T_g's when I had 40–45 wt.% vinyl acetate; ambiguous when I had 45–65 wt.% vinyl acetate	216,222, 325,330, 452,541, 672,756
	Vinyl chloride, chlorinated	Single T_g	Stated that there was a miscible region when I had 0.4–0.75 mol% ethylene and II had 0.4–0.8 mol% vinyl chloride	747
Ethylene-*co*-vinyl acetate-*co*-unnamed monomer	Vinyl chloride	Single T_g	Semicrystalline; I was du Pont de Nemours PB3041 (> 60% ethylene)	41
Ethylene-*co*-vinyl alcohol	Alkyl methacrylate	Single T_g; FTIR	II had an alkyl group of methyl, *n*-octyl or *n*-decyl (3 miscible blend systems); I had 21 mol% vinyl alcohol	1054
	Amide	Single T_g	I had 33 mol% vinyl alcohol; II was nylon 12 or nylon 6,12 (2 miscible blend systems)	4
	Copolyamide	Single T_g	II had 60 mol% nylon 6 units and 40 mol% nylon 12 units; I had 59 mol% vinyl alcohol	909
	4-Vinylpyridine	Single T_g	I had 68 mol% vinyl alcohol	1045
2-Ethylhexyl methacrylate	Styrene-*co*-hexyl methacrylate	Single T_g	I had 3–5% acrylic acid; II had 30% styrene and 5–15% 3-(dimethyl-amino)-2,2-dimethylpropyl methacrylate	766
N-ethyl-3-hydroxymethyl-carbazoyl methacrylate	ω-Hydroxyalkyl-3,5-dinitrobenzoyl methacrylate	Single T_g	II had an alkyl group of butyl, hexyl, pentyl or propyl (4 blend systems)	694
2-Ethyl-2-oxazoline	Acrylic acid	Single T_g	Formed complexes in water, methanol or dioxane	517
	Acrylic acid-*co*-styrene	Single T_g	II had 74 mol% acrylic acid	517
	Allyl alcohol-*co*-styrene	Single T_g; FTIR	II had 4.5 or 6.5 wt.% of hydroxyl group	974
	Aramid	Optical microscopy; light scattering	–	533
	Ether sulfone	Light scattering, transparency	–	599
	Hydroxyether of bisphenol-A (Phenoxy)	Single T_g; transparency	–	426
	Maleimide-*co*-styrene	Single T_g	II had 9.5–48.2 mol% maleimide	188
	Novolac	Single T_g	Formed complexes in methanol or acetone	517
	Sulfone, carboxylated	Single T_g	II had ≥ 0.93 degree of carboxylation	254

TABLE 1. *cont'd*

Polymer I of	Polymer II of	Method	Comments	Refs.
	p-Vinylphenol	Single T_g	Formed complexes in dioxane	517,857
	Vinylidene fluoride	Single T_g	>50 wt.% II	243
2-Ethyl-6-propyl-1,4-phenylene ether	Styrene	Single T_g	–	134
2-Fluoroethyl methacrylate	Alkyl methacrylate	Single T_g	II had an alkyl group of methyl or ethyl (2 miscible blend systems)	1153
3-Fluoropropyl methacrylate	Alkyl methacrylate	Single T_g	II had an alkyl group of methyl or tetrahydrofurfuryl (2 miscible blend systems)	1155
	Ester	Single T_g	II was butylene adipate or 2,2-dimethyl-1,3-propylene adipate (2 miscible blend systems)	1155
Glycidyl methacrylate	Acrylonitrile-*co*-styrene	Single T_g	II had 32.3–58.8 wt.% AN	1007
	Methyl methacrylate	Single T_g	II had $M_w \leq 4.25$ kg/mol	1007
	α-Methylstyrene	Single T_g	II had $M_w = 3.5$ kg/mol	1009
Glycidyl methacrylate-*co*-methyl methacrylate	Acrylonitrile-*co*-styrene	Single T_g	Miscibility depended on compositions of I and II	1007
Glycidyl methacrylate-*co*-styrene	Carbonate of tetramethylbisphenol-A	Single T_g	I had 1.6–37.1 wt.% GMA	1007
	2,6-Dimethyl-1,4-phenylene ether	Single T_g	I had 1.6–18.6 wt.% GMA	1007
	Vinylidene fluoride	Single T_g	I had $\leq$35.7 wt.% GMA	1009
Hexadecamethylene dodecamethylene dicarboxylate	Vinyl chloride	Single T_g	Semicrystalline	872
Hexafluoroisopropyl methacrylate	Alkyl methacrylate	Single T_g	II had an alkyl group of methyl or ethyl (2 miscible blend systems)	1153
Hexamethylene adipamide (nylon 6,6)	Ethylene terephthalate	FTIR; NMR	Blends prepared by coprecipitation; blends prepared by melt blending showed no sign of hydrogen-bonding	656
Hexamethylene adipate	Ester	Single T_g; microscopy	II was butylene sebacate or butylene succinate (2 miscible blend systems)	925
Hexamethylene isophthalate	Amide	Single T_g	Polymer II was nylon 6,5, nylon 6,7, nylon 6,8 or nylon 6,9 (4 miscible blend systems)	962
Hexamethylene sebacate	Vinyl acetate-*co*-vinylidene chloride	Single T_g	Semicrystalline; II was Saran C ($\geq$80% vinylidene chloride)	31
	Vinyl bromide	Single T_g	–	150
	Vinyl chloride	Single T_g	Semicrystalline when $\geq$50% I	872,900
Hexamethylene terephthalate	Hydroxyether of bisphenol-A (Phenoxy)	Single T_g	Semicrystalline when $\geq$75% I	735
	Vinyl chloride	Single T_g	Semicrystalline; deposited from some solvents as two phases	36
1-Hexene	1-Pentene	Single T_g	–	190
Hexyl methacrylate	Vinyl chloride	Single T_g; transparency	Especially when II was polymerized *in situ* (Ref. 846); stated as immiscible in Ref. 812	812,846, 850
	Vinyl chloride-*co*-vinylidene chloride	Single T_g; transparency	II was Saran ($\geq$80% vinylidene chloride)	409,812
3-Hydroxybutyrate	Cellulose acetate-butyrate	Single T_g	Semicrystalline	719,933,1183
	Cellulose acetate-proprionate	Single T_g; microscopy	Semicrystalline	719,1183
	Cellulose tributyrate	Single T_g; microscopy	Semicrystalline	1183
	Epichlorohydrin	Single T_g; microscopy; T_m depression	Semicrystalline	987,1183,1201
	Ethylene glycol	Single T_g	Semicrystalline	37,464,1237
	Ethylene glycol-*co*-lactide	Single T_g	II had 15 wt.% ethylene glycol	1241
	Lactide	Single T_g; microscopy	–	923,1079
	Methyl methacrylate	Single T_g	Blend had $\leq$20 wt.% I	1103,1183,1189
	Vinyl acetate	Single T_g	Semicrystalline	292,465
	Vinyl alcohol	NMR	Blend had a large amount of I	1239
	p-Vinylphenol	Single T_g; FTIR	–	1043
	Vinylidene fluoride	Single T_g; T_m-depression	Semicrystalline	407,414
3-Hydroxybutyrate-*co*-3-hydroxyvalerate	Acrylonitrile-*co*-butadiene-*co*-styrene	Single T_g	I had 16% hydroxyvalerate	180
	Vinyl chloride	Single T_g	I had 16 or 18% hydroxyvalerate	180,952
Hydroxyether of bisphenol-A (Phenoxy)	2,2-Dichloroethyl methacrylate	Single T_g; FTIR	–	1017
	2,2-Dichloroethyl methacrylate-*co*-methyl methacrylate	Single T_g; FTIR	II had $\leq$62 wt.% methyl methacrylate	1017

TABLE 1. *cont'd*

Polymer I of	Polymer II of	Method	Comments	Refs.
	Ether sulfone	Light scattering	–	714
	Ethylene oxide-*co*-propylene oxide	Single T_g	II had ≥22 mol% ethylene oxide	1025
	Methyl methacrylate	Single T_g; NMR	II was atactic, isotactic or syndiotactic	112,218, 775,910
	Vinyl methyl ether	Single T_g; IGC	–	690,819,820,996
	Vinylpyridine	Single T_g; FTIR	II was 2- or 4-vinylpyridine (2 miscible blend systems)	981
	N-vinylpyrrolidone	Single T_g; transparency: FTIR	–	1253
	Urethane	Single T_g	II was made from 1/1/2 = polycaprolactone diol (M_n = 2.1 kg/mol)/ 1,4-butanediol/4,4′-diphenylmethane diisocyanate	730
Hydroxyether of bisphenol-A, benzoylated	*N*-vinylpyrrolidone	Single T_g; FTIR	–	1002
Hydroxyether of bisphenol-A, modified	2-Vinylpyridine	Single T_g; FTIR	OH groups in I was converted to benzoate, acetate or methoxy group	989
Hydroxyether of phenolphthalein	Butylene terephthalate	Single T_g	–	310
	Carbonate of bisphenol-A	Single T_g	–	310
	Ether sulfone	Single T_g; FTIR	–	306
	Ethylene glycol	Single T_g	–	309
β-Hydroxyethyl-3,5-dinitrobenzoyl methacrylate	*N*-alkyl-3-hydroxymethylcarbazoyl methacrylate	Single T_g	II had an alkyl group of butyl, decyl, dodecyl, ethyl, hexadecyl, hexyl, methyl, octyl or tetradecyl (9 miscible blend systems)	693
	N-(2-hydroxyethyl)carbazoyl methacrylate	Single T_g	–	693
2-Hydroxyethyl methacrylate	Acrylamide-*co*-styrene	Single T_g; NRET	II had 40, 47 or 52 mol% acrylamide	955,1248
p-(2-Hydroxy-hexafluoroisopropyl) -α-methylstyrene-*co*-styrene	Butyl acrylate	Single T_g	I had ≥1.2 mol% OH-containing monomer	90
	Butyl methacrylate	Single T_g	I had >2.8 mol% OH-containing monomer	1166
	Methyl methacrylate	Single T_g	I had ≥1.9 mol% OH-containing monomer	90
	Methyl methacrylate-*co*-2-vinylpyridine	Single T_g	I had ≥6 mol% OH-containing monomer	377
p-(2-Hydroxy-hexafluoro-isopropyl)styrene-*co*-styrene	Aramide	Single T_g; transparency	I had 60 mol% styrene; two T_g's when I had 83 mol% styrene; II was iminotrimethylhexamethylene-iminoterephthaloyl	571,646
	Butyl methacrylate	Single T_g; NRET	I had >1 mol% OH-containing monomer; formed complexes when I had 18 mol% OH	1166
	α,ω-Decanedicarboxylic-*co*-hexanediamine acid (nylon 6,12)	Single T_g	Semicrystalline	454
	Hydroxypropyl L-glutamate	Single T_g; light scattering; microscopy	Blend had <50 vol% II	971
	Methyl methacrylate	Single T_g; transparency; NMR; FTIR; WAXD; NRET	I had >8 mol% OH; formed complexes when I had 24 mol% OH; II was isotactic or syndiotactic (Ref. 1116,1117)	571,646, 1021,1116, 1117,1241
	Vinyl acetate	Single T_g; transparency	I had 90.3 mol% styrene	571,646
	Vinyl methyl ether	Single T_g; transparency	I had 83.3–99.9 mol% styrene	571,572,646
	Vinyl methyl ketone	Transparency	I had 90.3 mol% styrene	567
2-Hydroxypropyl methacrylate	Tertiary amide	Single T_g; FTIR	Formed complexes; II was dimethylacrylamide, *N*-methyl-*N*-vinylacetamide or ethyloxazoline (3 blend systems)	975
Imide	Ether ketone ketone	Single T_g	I was made from pyromellitic dianhydride (PMDA) and 4,4′-bis(3-aminophenoxy) biphenyl	1179
	Ether ketone	Single T_g	I was the same as the previous system; II was Victrex 220P; blend had ≤50 wt.% I	1179
	Imide	X-ray diffraction	I was made from PMDA and oxydianiline; II was made from	391

TABLE 1. *cont'd*

Polymer I of	Polymer II of	Method	Comments	Refs.
			PMDA and *p*-phenylenediamine; <90% II in blend	
	Imide	Single T_g	I was made from 2,2′-bis(3,4′-dicarboxyphenyl)hexafluoro-propane dianhydride (6FDA) and 2,2′-bis(3-aminophenyl)-hexafluoropropane (3,3′-6F-diamine); II was made from 6FDA and 2,2′-bis (4-aminophenyl)hexafluoropropane (4,4′-6F-diamine)	130
	Imide	Single T_g	I was made from 4,4′-biphthalic anhydride (BPDA) and 3,3′-6F-diamine; II was made from BPDA and 4,4′-6F-diamine	130
	Imide	Single T_g	I was made from 3,3′4,4′-benzophenone-tetracarboxylic dianhydride (BTDA) and 3,3′-6F-diamine; II was made from BTDA and 4,4′-6F-diamine	130
	Imide	Single T_g	I was made from 3,3′,4,4′-diphenyl-ethercarboxylic dianhydride (OPDA) and 3,3′-6F-diamine; II was made from OPDA and 4,4′-6F-diamine	130
	Imide	Single T_g	I was made from PMDA/BPDA/3,3′-6F-diamine = 25/25/50; II was made from PMDA/BPDA/4,4′-6F-diamine = 25/25/50	130
	Imide	Single T_g	I was made from PMDA/BTDA/3,3′-6F-diamine = 25/25/50; II was made from PMDA/BTDA/4,4′-6F-diamine = 25/25/50	130
	Imide	Single T_g	I was made from PMDA/OPDA/3,3′-6F-diamine = 25/25/50; II was made from PMDA/BTDA/4,4′-6F-diamine = 25/25/50	130
	Imide	Single T_g; WADX; SAXS	I was made from 3,3′,4,4′-diphenyltetra-carboxylic dianhydride (DBTA) and oxydianiline (DOA); II was made from 4,4′-thiodiphthalic anhydride and ODA	1244
	Imide	Single T_g	I was made from DBTA and 3,3′-hexa-fluoroisopropylidene dianiline (3,3′-HIPD); II was made from DPTA and 4,4′-hexafluoroisopropylidene dianiline (4,4′-HIPD)	957
	Imide	Single T_g	I was made from 5,5′-[2,2,2-trifluoro-1-(trifluoromethyl)ethylidene] bis-1,3-isobenzofuranedione (A) and HIPD; II was made from A and 4,4-HIPD	957
	Imide	Single T_g	I was made from BTDA and 3,3′-HIPD; II was made from BTDA and 4,4′-HIPD	957
2-Iodoethyl methacrylate	Acrylonitrile-*co*-*p*-methylstyrene	Single T_g	II had 21–42 wt.% AN	1106
	Acrylonitrile-*co*-styrene	Single T_g	II had 13–51 wt.% AN	1106
	Ester	Single T_g	II was butylene adipate, caprolactone, 2,2-dimethyl-1,3-propylene adipate or hexamethylene sebacate (4 miscible blend systems)	1111
	Tetrahydrofurfuryl methacrylate	Single T_g	–	1107
cis-Isoprene	Butadiene-*co*-1,2-vinylbutadiene	Single T_g	II had ≥32.3% vinylbutadiene	420
	cis-Pentenamer	Single T_g	–	77
	Vinylethylene	Single T_g; NMR	II had 86% 1,2-butadiene	570,697,700,810,811
Isoprene, chlorinated	Ethylene-*co*-vinyl acetate	Single T_g; transparency	Semicrystalline; commercial samples	503,665
Isoprene, modified by hexafluoroisopropanol group	Alkyl methacrylate	Single T_g; FTIR	II had an alkyl group of methyl or *n*-butyl (2 miscible blend systems)	959
	Ethylene-*co*-methyl acrylate	Single T_g; FTIR	II had 40 or 75 wt.% methyl acrylate	959

TABLE 1. *cont'd*

Polymer I of	Polymer II of	Method	Comments	Refs.
	Ethylene-*co*-methyl methacrylate	Single T_g; FTIR	II had 50 wt.% methyl methacrylate	959
	Ethylene-*co*-vinyl acetate	Single T_g; FTIR	II had 35 or 70 wt.% vinyl acetate	959
	Methyl acrylate	Single T_g; FTIR	–	959
	Methyl acrylate-*co*-styrene	Single T_g; FTIR	II had 28 wt.% methylacrylate	959
Isoprene-*stat*-*N*-(2-hydroxyethyl) carbazole methacrylate	Styrene-*stat*-*N*-itaconimidyl-3,5-dinitrobenzoate	Single T_g	Polymer had at least 20 mol% of electron-donor or electron-acceptor group	963
Isoprene-*b*-methyl methacrylate	Acrylonitrile-*co*-styrene	Single T_g	II had 22 wt.% acrylonitrile	1049
	p-(2-Hydroxy-hexafluoroisopropyl)-α-methylstyrene-*co*-styrene	microscopy	II had ≥ 1.6 mol% OH groups	1254
Isopropenyl methyl ketone	*p*-Vinylphenol	Single T_g; NMR; FTIR	–	1035
Isopropyl acrylate	Isopropyl methacrylate	Single T_g; transparency	–	453
Maleic acid-*co*-styrene	Vinyl butyral	Transparency	I was Daidou Kogyo Styrite HS-2	452
Maleic anhydride-*alt*-α-methylstyrene	2,6-Dimethyl-1,4-phenylene ether, sulfonylated	Single T_g	II had <55 mol% sulfonylation	838
Maleic anhydride-*co*-styrene	Caprolactone	Single T_g	I had 14 or 25 wt.% maleic anhydride; semicrystalline	192
	Carbonate of tetramethylbisphenol-A	Single T_g	I had <12% maleic anhydride	1008
	2,6-Dimethyl-1,4-phenylene ether	Single T_g	I had <10% maleic anhydride	1008
	2,6-Dimethyl-1,4-phenylene ether, sulfonylated	Single T_g	I was alternating copolymer and had <55 mol% sulfonylation	838
	Ethyl methacrylate	Single T_g	I had 0–33 wt.% maleic anhydride	73
	Methyl methacrylate	Single T_g; NMR; FTIR	I had 8–33 wt.% maleic anhydride	73,999
	n-Propyl methacrylate	Single T_g	I had 0–18.1 wt.% maleic anhydride	73
	Vinyl methyl ether	Single T_g	I had 4.7 wt.% maleic anhydride	862
Maleimide-*alt*-α-methylstyrene	2,6-Dimethyl-1,4-phenylene ether, sulfonylated	Single T_g	Depended on degree of sulfonylation of II	837
Methacrylate, liquid crystalline	Methacrylate, liquid crystalline	Single T_g; microscopy	I had electron-donating (carbazolyl methylene)aniline groups; II had electron-accepting groups	1077
Methacrylic acid-*co*-α-methylstyrene	Butyl methacrylate-*co*-4-vinylpyridine	Single T_g; FTIR	I had 50.6 mol% methacrylic acid (MA); II had 18 or 26 mol% vinylpyridine (VP)	1131
	Ethyl methacrylate-*co*-4-vinylpyridine	Single T_g; FTIR	I had 50.6 mol% MA; II had 23 mol% VP	1131
	Methyl methacrylate-*co*-4-vinylpyridine	Single T_g; FTIR	I had 50.6 mol% MA; II had 8 mol% VP	1131
Methacrylic acid-*co*-styrene	Ethyl methacrylate	Single T_g; fluorescence study	Miscible when cast from toluene or dioxane; immiscible when cast from chloroform; I had 93.4–96.7 mol% styrene	103
Methacryloyl glycine-*co*-styrene	Ethyl methacrylate	Fluorescence study	Miscible when cast from toluene; immiscible when cast from chloroform; I had 93.8–97.2 mol% styrene	103
Methacrylonitrile-*co*-α-methylstyrene	Vinyl chloride	Single T_g	I was azeotropic	423
Methacrylonitrile-*co*-*p*-methylstyrene	*n*-Butyl methacrylate	Single T_g	II had 12–28 wt.% of methacrylonitrile (MAN)	944
	Ethyl methacrylate	Single T_g	II had 12–55 wt.% MAN	944
	Methyl methacrylate	Single T_g	II had 19–70 wt.% MAN	944
	Isopropyl methacrylate	Single T_g	I had 19–34 wt.% MAN when II had $M_n = 161$ kg/mol; I had 16–34 wt.% MAN when II had $M_n = 41.6$ kg/mol	944
	n-Propyl methacrylate	Single T_g	I had 12–43 wt.% MAN	944
Methacrylonitrile-*co*-styrene	*t*-Butyl methacrylate-*co*-methyl methacrylate	Single T_g	Miscibility depended on composition of I and II	1139
	Cyclohexyl methacrylate-*co*-methyl methacrylate	Single T_g	Miscibility depended on composition of I and II	1139
	Ethyl methacrylate	Single T_g	I had 4.5–44 wt.% methacrylonitrile (MAN)	943
	Methyl methacrylate	Single T_g; transparency;	Miscibility range varied in various fluorescence spectroscopy studies especially at the low MAN end	970,986, 1018, 1139

TABLE 1. *cont'd*

Polymer I of	Polymer II of	Method	Comments	Refs.
	Isopropyl methacrylate	Single T_g; transparency	I had 12–38 wt.% MAN when II had $M_n = 161$ kg/mol; I had 8–43 wt.% MAN when II had $M_n = 41.6$ kg/mol	943
	n-Propyl methacrylate	Single T_g; transparency	I had 2–32 wt.% MAN	943
4-[[6-(Methacryloyloxy)hexyl]-oxy]-*N*-[(9-methyl-2-carbazolyl) methylene]aniline	4-[[6-(Methacryloyloxy)hexyl] oxy]-*N*-(4′-nitrobenzylidene) aniline	Single T_g	Polymer I and polymer II were liquid crystalline	1076
4-[[1-[4(-Methoxyphenyl)azo] phenyl]-4-oxy]-3-propyl] oxy]styrene	4-[[1-[(4-cyanobiphenyl)-4′)oxy]-3-propyl]oxy]styrene	Single T_g	Blend showed liquid crystallinity	1042
p-Methoxystyrene-*co*-*p*-vinyl-phenol	Alkyl acrylate	Single T_g; FTIR	II had an alkyl group of methyl or ethyl (2 miscible blend systems); I had 33–63 mol% vinylphenol	1177
	Vinyl acetate	Single T_g; FTIR	I had 33–63 mol% vinylphenol	1177
Methyl acrylate	Epichlorohydrin	Single T_g	–	226
	Epichlorohydrin-*co*-ethylene glycol	Single T_g	I had 50 mol% epichlorohydrin (Hydrin 200)	226
	Ethylene glycol	Single T_g	–	226
	Nitrocellulose	Single T_g	–	416
	Vinyl acetate	Single T_g; transparency; NMR	Probably formed two phases when deposited from some solvents (Refs. 601)	453,601,615 1196
	Vinyl chloride-*co*-vinylidene chloride	Single T_g; transparency	II was Saran (≥ 80% vinylidene chloride); I had MW = 1.0 kg/mol; two T_g's when I had MW = 576 kg/mol in Ref. 870	812,870
	Vinylidene fluoride	Single T_g; transparent melt	Semicrystalline	844,1122
Methyl acrylate-*co*-vinylcarbazole	Methyl methacrylate-*co*-2(3,5-dinitrobenzoyl)oxyethyl methacrylate	Single T_g	Both I and II had >27 mol% monomer with interactive groups	705
	Styrene-*co*-2(3,5-dinitrobenzoyl) oxyethyl methacrylate	Single T_g	Both I and II had > 12 mol% monomer with interactive groups	173
Methyl 1-bicyclobutane-carboxylate	Acrylonitrile-*co*-styrene	Single T_g; transparency	II had 24–38 wt.% acrylonitrile	202
	Ethylene glycol	Single T_g; transparency	≤ 20 wt.% II	202
2-Methyl-6-ethyl-1,4-phenylene ether	Styrene	Single T_g	–	134
α-Methyl-α-ethyl-β-propiolactone	Vinyl chloride	Single T_g	Semicrystalline when blend had 75% I	33
Methyl methacrylate	Acrylonitrile-*co*-methyl methacrylate-*co*-styrene	Single T_g	II had 40/39.1/20.9 or 61.1/19.6/19.3 = styrene/methyl methacrylate/ acrylonitrile	620
	4′-[[2-(Acryloyloxy)ethyl]-ethylamino]-4-nitroazobenzene	Single T_g; NMR	–	1228
	4′-[[2-(Acryloyloxy)ethyl]-ethylamino]-4-chloro-4-nitro-azobenzene	Single T_g; NMR	–	1228
	p-*tert*-Butylphenol-*co*-formaldehyde	Single T_g; FTIR; WAXD	–	647,1056
	Carbon monoxide-*alt*-propylene	Single T_g; FTIR; NMR	–	1229
	Carbonate	Single T_g; transparency	II was carbonate of bisphenol-F or bisphenol-AF (2 miscible blend systems)	426
	Carbonate of bisphenol chloral	Single T_g; NMR	–	110.426,673,983
	Copolycarbonate of bisphenol-A and hexafluorobisphenol-A	Single T_g; transparency	II had 4.5–14.0 wt.% hexafluoro-bisphenol-A	430
	p-Chlorophenol-*co*-formaldehyde	Single T_g; FTIR	–	647
	Epichlorohydrin-*co*-ethylene glycol	Single T_g	–	224
	Ethyl acrylate	Single T_g	–	156
	Ethyl methacrylate	Single T_g	Made from slurries of polyethyl methacrylate and methyl methacrylate; inherently unstable, phase separation upon heating	763
	Formaldehyde-*co*-*p*-nitrophenol	Single T_g; FTIR	–	647
	Formaldehyde-*co*-phenol	Single T_g; FTIR	–	647
	Hexafluoroacetone-*co*-vinylidene fluoride	Single T_g	–	443

TABLE 1. *cont'd*

Polymer I of	Polymer II of	Method	Comments	Refs.
	N-Maleimide-*co*-styrene	Single T_g; FTIR	II had 8, 14 or 21 wt.% *N*-maleimide	1213
	Methoxymethyl methacrylate	Single T_g	–	264
	Methyl acrylate	Single T_g	–	156
	α-Methylstyrene	Single T_g	–	167,765
	Nitrocellulose	No phase separation in solution or films	–	199,296,452,651
	Novolac	Single T_g; FTIR	II had MW about 1.0 kg/mol and was formaldehyde and 13/17/70 mol% = *p-tert*-butylphenol/*m*-cresol/*o*-cresol or formaldehyde and 15/17/68 mol% = 2-*t*-butylphenol/*m*-cresol/*o*-cresol; I was isotactic, atactic or syndiotactic	221,434,473
	Propylene glycol	Single T_g; SAXS	I had MW = 550 kg/mol; II had MW = 1.0–3.9 kg/mol	527
	Tetrafluoroethylene-*co*-vinylidene fluoride	Single T_g; T_m-depression	II had 80 mol% vinylidene fluoride	113,324
	Trifluoroethylene-*co*-vinylidene fluoride	Light scattering; FTIR; T_m-depression	II had 58 or 75 mol% vinylidene fluoride	713,1066
	Vinyl acetate	Single T_g; FTIR; LS; microscopy	Miscible when cast from chloroform or cyclohexanone; immiscible when cast from tetrahydrofuran or melt blended	302,602, 726,777, 778,928, 1092
	Vinyl acetate-*co*-vinyl chloride	Single T_g; transparency	II had 5.9–15.1 vol% vinyl acetate	236,296,452, 497,651
	Vinyl chloride	Single T_g; transparency	Especially when II was polymerized *in situ* (Ref. 846); I of all tacticities miscible with II (Ref. 338); increase in isotactic content and mol. wt. of I reduced miscibility with II (Ref. 893)	66,338,368, 641,642,653, 812,846,850, 892,893,895
	Vinyl chloride, chlorinated	Single T_g; FTIR	II had 63–68 wt.% Cl; I was atactic, isotactic of syndiotactic (1204)	506,833,1204
	Vinyl chloride-*co*-vinylidene chloride	Single T_g; transparency	II was Saran (>80% vinylidene chloride) or 86.5 wt.% vinylidene chloride; semicrystalline when ≥20% II and I was isotactic, and when ≥75% II and I was atactic for the second II	409,506, 812,870
	Vinyl chloroacetate	Single T_g	–	179
	Vinylidene fluoride	Single T_g; NMR	Semicrystalline when >35–65% II; I was isotactic, atactic or syndiotactic	124,293, 320,342,361, 569,618,630, 643,644,696
Methyl methacrylate, imidized	Acrylonitrile-*co*-styrene	Single T_g	I had 53–91 wt.% imidized units; II had 5.7–33 wt.% acrylonitrile; miscibility depended on extent of imidization of I and acrylonitrile content of II	230,1123
	Vinyl chloride	Single T_g	I had 53–85 wt.% imidized units	230
Methyl methacrylate-*co*-styrene	Copolycarbonate of bisphenol-A and tetramethylbisphenol-A	Single T_g; transparency	I had ≤33 wt.% methyl methacrylate; II had ≤15 wt.% bisphenol-A	431
	Copolycarbonate of hexafluoro-bisphenol-A and tetramethyl-bisphenol-A	Single T_g	I had 9, 20 or 33 wt.% methyl methacrylate; II had 20 wt.% hexafluorobisphenol-A	1194
Methyl methacrylate-*co*-vinylpyridine	Acrylic acid-*co*-butyl acrylate	Single T_g; FTIR	I had 13–20 mol% vinylpyridine; II had 13–20 mol% acrylic acid	385
2-Methyl-2-oxazoline	Allyl alcohol-*co*-styrene	Single T_g; FTIR	II had 6.5 wt.% OH group	978
	Hydroxyether of bisphenol-A	Single T_g; FTIR	–	978
	2-Hydroxypropyl methacrylate	Single T_g; FTIR	–	978
	Vinyl alcohol	Single T_g; FTIR	–	913
	Vinyl chloride	Single T_g	I <50 wt.% in blend	442
	Vinyl fluoride	Single T_g	I <50 wt.% in blend	442
	p-Vinylphenol	Single T_g; FTIR	–	978
2-Methyl-1-pentene sulfone	Novolac	Single T_g	II had MW = 1.0 kg/mol and was formaldehyde and 13/17/70 mol% = *p-tert*-butylphenol/*m*-cresol/*o*-cresol or formaldehyde and 15/17/68 mol% = 2-*tert*-butylphenol/*m*-cresol/*o*-cresol	221

TABLE 1. *cont'd*

Polymer I of	Polymer II of	Method	Comments	Refs.
2-Methyl-6-propyl-1, 4-phenylene ether	Styrene	–	–	134
α-Methyl-α-*n*-propyl-β-propiolactone	Vinyl chloride	Single T_g	Semicrystalline when >50% I	32,33
α-Methylstyrene	Alkyl methacrylate	Single T_g; transparency	II had an alkyl group of cyclohexyl, ethyl or *n*-propyl (3 miscible blend systems)	116,765
	Cyclohexyl acrylate	Single T_g; transparency	–	765
p-Methylstyrene	Cyclohexyl acrylate	Single T_g; transparency	–	765
	Cyclohexyl methacrylate	Single T_g; transparency	–	116,765
	2,6-Dimethyl-1,4-phenylene ether, bromobenzylated	Single T_g; transparency	II had 9, 16 or 37% bromination	261
α-Methylstyrene-*co*-4-(2-hydroxyethyl)-α-methylstyrene	Alkyl acrylate	Single T_g	I had 6, 41, 72 or 89 mol% α-methylstyrene; II had an alkyl group of ethyl, *tert*-butyl or methyl (3 blend systems)	968
	Alkyl methacrylate	Single T_g	I had 6, 41, 72 or 89 mol% α- methylstyrene; II had an alkyl group of ethyl, *tert*-butyl or methyl (3 blend systems)	968
	Dialkyl itaconate	Single T_g	I had 6, 41, 72, or 89 mol% α-methylstyrene; II had a dialkyl group of dimethyl, diethyl, di-*tert*-butyl or di-*n*-propyl (4 blend systems)	968
	Vinyl acetate	Single T_g	I had 6, 41, 72 or 89 mol% α-methylstyrene	969
	4-Vinylpyridine	Single T_g	I had 6, 41, 72 or 89 mol% α-methylstyrene	969
	N-Vinyl pyrrolidone	Single T_g	I had 6, 41, 72 or 89 mol% α-methylstyrene	969
α-Methylstyrene-*co*-[4-(1,1,1-trifluoro-2-hydroxyethyl)-α-methylstyrene	Alkyl acrylate	Single T_g	I had 23, 47, 60, 84 or 93 mol% α-methylstyrene; II had an alkyl group of methyl, ethyl or *tert*-butyl (3 blend systems)	968
	Alkyl methacrylate	Single T_g	I had 23, 47, 60, 84 or 93 mol% α-methylstyrene; II had an alkyl group of methyl, ethyl or *tert*-butyl (3 blend systems)	968
	Dialkyl itaconate	Single T_g	I had 23, 47, 60, 84 or 93 mol% α-methylstyrene; II had a dialkyl group of dimethyl, diethyl, di-*n*-propyl or di-*tert*-butyl (4 blend systems)	968
	Vinyl acetate	Single T_g	I had 23, 47, 60, 84 or 93 mol% α-methylstyrene	969
	4-Vinylpyridine	Single T_g	I had 23, 47, 60, 84 or 93 mol% α-methylstyrene	969
	N-Vinyl pyrrolidone	Single T_g	I had 23, 47, 60, 84 or 93 mol% α-methylstyrene	969
N-Methyl-*N*-vinylacetamide	Allyl alcohol-*co*-styrene	Single T_g; FTIR	II had 4.5 or 6.5 wt.% OH group; formed complexes in 2-butanone	973
Monomethyl itaconate	Thiocarboate	Single T_g	II had methyl, ethyl or propyl side groups	669
Natural rubber, epoxidized	Acrylic acid-*co*-ethylene	Single T_g	I had 50 mol% epoxidation; II had 6 mol% acrylic acid; blend had >50 wt.% II	1134
	Alkyl acrylate-*co*-vinylidene chloride	Single T_g	I had 50 mol% epoxidation; II had 10% alkyl acrylate	400
	Chloroprene	Single T_g	I had 50 mol% epoxidation	1065
	Ethylene, chlorinated	Single T_g	I had 50 mol% epoxidation; II had 25 or 48% Cl	543
	Ethylene, chlorosulfonated	Single T_g	I had 25 mol% epoxidation; II was Hypalon 40	590
	Novolac	Single T_g	I had 50 mol% epoxidation	401
	Propylene, chlorinated	Single T_g	I had 50 mol% epoxidation	400
	Vinyl chloride	Single T_g	I had 50 mol% epoxidation	507,827,828
	Vinyl chloride, plasticized	Single T_g	I had 50 mol% epoxidation; II had 40 phr dioctyl phthalate	826

References page VI-461

TABLE 1. *cont'd*

Polymer I of	Polymer II of	Method	Comments	Refs.
Neopentyl glycol adipate (2,2-dimethyl-1,3-propylene adipate)	Hydroxyether of bisphenol-A (Phenoxy)	Single T_g; transparency	–	332
	Vinyl acetate-*co*-vinyl chloride	Single T_g; transparency	II had 2 or 17 wt.% vinyl acetate	276
	Vinyl chloride	Single T_g; transparency	–	277
	Vinyl chloride-*co*-vinylidene chloride	Single T_g	Semicrystalline; II was Saran (86.5 wt.% vinylidene chloride)	868
	Vinylidene fluoride	Clear melt although refractive indices very different; T_m-depression	Semicrystalline	287
Neopentyl glycol succinate (2,2-dimethyl-1,3-propylene succinate)	Epichlorohydrin	Single T_g; transparency	–	223
	Hydroxyether of bisphenol-A (phenoxy)	Single T_g; transparency	Semicrystalline ≤20 wt.% II	332
	Vinyl chloride	Single T_g; transparency	–	900
	Vinyl chloride-*co*-vinylidene chloride	Single T_g	≤60 wt.% I; possible second T_g when >60 wt.% I; semicrystalline	868
Nitrocellulose	Ester	Single T_g; FTIR	I had 12.62 or 13.42% N; II was butylene adipate, caprolactone, ethylene adipate or valerolactone (4 miscible blend systems)	393
	Vinyl acetate	Single T_g; clear films	–	236,421,452
Novolac	*n*-Butyl methacrylate	Single T_g; FTIR	–	434
	Vinyl acetate	Single T_g	I had MW about 1.0 kg/mol and was formaldehyde and 15/17/68 mol% = 2-*tert*-butylphenol/*m*-cresol/*o*-cresol	221
	Vinyl methyl ether	Single T_g	I had MW about 1.0 kg/mol and was formaldehyde and 13/17/70 mol% = *p*-*tert*-butylphenol/*m*-cresol/*o*-cresol	221
Phenolphthalein polyether ether ketone	Epoxy	Single T_g	–	312
	Hydroxyether of bisphenol-A (phenoxy)	Single T_g	–	308,312
	Sulfone	Single T_g	–	308,311
	N-Vinylpyrrolidone	Single T_g	–	307
Phenolphthalein polyether ether sulfone	*N*-Vinylpyrrolidone	Single T_g	–	307
Phenol–formaldehyde	*N,N*-Dimethylacrylamide	Single T_g	Formed complexes from acetone, dioxane and ethyl acetate	881
	Methyl methacrylate-*co*-styrene	Single T_g	II had >20 wt.% methyl methacrylate	433
Phenyl acrylate	Vinyl benzoate	Single T_g; transparency	–	535
Phenylene, sulfonated	Ethyl acrylate-*co*-4-vinylpyridine	Single T_g	–	592
p-Phenylene benzobisoxazole	Amide	Single T_g; dielectric measurements; WAXS; LS	II was Zytel 330 (Du Pont)	945
	Amide	Single T_g; microscopy; dielectric measurements	II was nylon-6,6; semicrystalline	1084
2,2-(*m*-Phenylene)-5,5′-bibenzimidazole	Arylate	Single T_g	–	125
	Carbonate of bisphenol-A	FTIR	–	594
	Imide	Single T_g; FTIR	II was made from 3,3′,4,4′-benzophenonetetracarboxylic dianhydride and 3,3′-diaminobenzophenone (LARC TPI)	299
	Imide	Single T_g; FTIR	II was 2,2′-bis(3,4-dicarboxyphenoxy)phenylpropane-2-phenylene bisimide(Ultem 1000)	507,509,748, 823
	Imide	Single T_g; FTIR	II was made from 3,3′,4,4′-benzophenone-tetracarboxylic dianhydride and 5,6-amino-1-(4′-aminophenyl)-1,3,3′-trimethylindam (XU 218)	115,507, 748
	Imide	Single T_g; FTIR	II was made from benzophenone-tetracarboxylic dianhydride and 4/1 mixture of 2,4-toluenediisocyanate	507,781

TABLE 1. *cont'd*

Polymer I of	Polymer II of	Method	Comments	Refs.
			and 4,4′-diphenylmethanediisocyanate(PI 2080)	
	Imide sulfone	Single T_g; FTIR	II was made from 3,3′,4,4′-benzophenonetetracarboxylic dianhydride and 3,3′-diaminodiphenyl sulfone	105,369, 492
	Imide sulfone, fluorinated	Single T_g; FTIR	≥80% I	369
	Siloxaneimide, segmental copolymer	Single loss tangent peak	II was 3,3′,4,4′-benzophenone-tetracarboxylic dianhydride and 3,3′-diaminodiphenylsulfone based polyimide and dimethylsiloxane segmental copolymer	105
m-Phenylene isophthalamide	Aramide	Single T_g	II was a copolyamide of 1,6-hexanediamine, caprolactam and terephthalic acid (BASF Ultramid T) or Selar 3426 (Du Pont) (2 blend systems)	993
	Hexamethylene isophthalamide	Single T_g	Semicrystalline	81,993
	Heptamethylene isophthalamide	Single T_g	Semicrystalline	81
	m-Xylene adipamide	Single T_g	Semicrystalline	993
Phenylene sulfide	Phenylene sulfide ether	Single T_g	Semicrystalline	926
p-Phenylene terephthalamide	Amide	Single T_g; FTIR	Semicrystalline; II was nylon 6 or nylon 6,6 (2 miscible blend systems)	477
	p-Phenylene 1,3,4-oxadizole	Miscroscopy; FTIR	–	1080
n-Propyl acrylate	Vinyl chloride	Single T_g; transparency	–	850
n-Propyl methacrylate	Vinyl chloride	Single T_g; transparency	–	319,649,812,850
	Vinyl chloride-*co*-vinylidene chloride	Single T_g; transparency	Semicrystalline when ≥65% II; II was Saran (≥80% vinylidene chloride) or 86.6 wt.% vinylidene chloride	409,812, 870
Propyloxazoline	Styrene	Single T_g	<25 wt.% I in blend	442
Propylene	Hydrogenated oligocyclopentadiene	Melting point depression; WAXS; SANS	–	550
Propylene, chlorinated	2,2-Dimethyl-1,3-propylene adipate	Single T_g; transparency	I had 67 wt.% Cl	287
Rubber, chlorinated	Vinyl methyl ether	Phase diagram	–	250
Styrene	Carbonate of tetramethylbisphenol-A	Single T_g; light scattering; NMR; PALS	Semicrystalline after long annealing	316,359,428, 741,1100,1230,1231
	2-Chlorostyrene	Negative volume change of mixing	–	814
	Copolycarbonate of bisphenol-A and tetramethylbisphenol-A	Single T_g; transparency	II had ≥85 wt.% tetramethylbisphenol-A	431
	Cyclohexyl acrylate	Single T_g	–	765
	Cyclohexyl methacrylate	Single T_g; transparency	–	116,621,765
	Cyclohexyl methacrylate-*co*-methyl methacrylate	Single T_g	II had ≥21.6% cyclohexyl methacrylate	621
	2,6-Dimethyl-1,4-phenylene ether, bromobenzylated	Single T_g	II had ≤76% bromination	259
	2,6-Dimethyl-1,4-phenylene ether, sulfonated	Single T_g	II had <1.9% sulfonation	345
	2,6-Dimethyl-1,4-phenylene ether-*co*-2,3,6-trimethyl-1,4-phenylene oxide	Single T_g	I was atactic or isotactic; II had <20 mol% 2,3,6-trimethyl-1,4-phenylene oxide	638
	Ethyl methacrylate	Single T_g	Miscible when melt blended	72
	o-Fluorostyrene-*co*-*p*-fluorostyrene	Single T_g	II had 10 or 23 mol% *p*-fluorostyrene	1144
	α-Methylstyrene	Single T_g	–	710,722,822,865,875
	n-Propyl methacrylate	Single T_g	Miscible when melt blended	72
	Vinyl methyl ether	Single T_g; transparency; NMR; attenuated total reflectance IR	Two phases when deposited from some solvents	43,44,62,126,475, 565,616,964
	Vinyl methyl ether	Single T_g	I was syndiotactic; blend had <20 wt.% I	954
	Vinyl methyl ether	SANS; NMR	I was atactic or isotactic	915,918,1199
Styrene, sulfonated	Alkylene glycol amine-terminated	FTIR	I had 4.5 mol% sulfonation; II had $M_n = 0.9$ kg/mol (Jeffamine ED-900)	246
	N,*N*-Dimethylacrylamide	Transparency; NMR	I had 12 mol% sulfonation	487,1064
	2,6-Dimethyl-1,4-phenylene ether	Single T_g	I had <2.6% sulfonation	345
	10,12-Docosadiynylene diisonicotinate	Single T_g; FTIR	I had 9 mol% sulfonation	990,991
	Ethylene oxide	Single T_g	I had 1.35 or 4.51 mol% SO_3H; II end-capped with propylamine groups	861

References page VI-461

TABLE 1. *cont'd*

Polymer I of	Polymer II of	Method	Comments	Refs.
	Bis[2-[2-(2-methoxyethoxy)ethoxy] ethyl itaconate	Single T_g; FTIR	I had 14 mol% sulfonation	1086
	Methyl methacrylate	Single T_g; transparency	I had 12 mol% sulfonation	487
	Methyl methacrylate-*co*-4-vinylpyridine	NMR	I had 9.9% sulfonation; II had 11.1% vinylpyridine	604
	Urethane	FTIR	I had 7.9 mol% sulfonation	801
Styrene, sulfonated and metal-neutralized	Amide	Single T_g; FTIR; SAXS	I was lightly sulfonated and Mg- or Mn-neutralized; II was nylon 6	1038
	Amide	Single T_g; FITR; SAXS	I had 9.7 mol% sulfonation and Li-neutralized; II was nylon 4	1138
	Amide	Single T_g	I had 9.8 mol% sulfonation and Li-neutralized; II was nylon 6,6 or nylon 6,10 (2 blend systems)	1135
	Amide	Single T_g; FTIR; SAXS	I had 5.4 or 9.8 mol% sulfonation and Li-neutralized; II was nylon 6	1168,1223
	Amide	Single T_g; NMR; FTIR; SAXS	I had 6.5–9.0 mol% sulfonation and Zn-neutralized; II was nylon 6	1083,1223
	Ethyl acrylate-*co*-4-vinylpyridine	FTIR	I had 2.1–7.3 mol% sulfonation and Zn-neutralized; II had 2.4–10.6 mol% vinylpyridine	1176
Styrene-*co*-styrene-4-carboxylic acid	*N*,*N*-Dimethylacrylamide	Single T_g; transparency	I had 25 or 54 mol% acid groups	487
	Methyl methacrylate	Single T_g; transparency	I had 25 mol% acid units	487
Styrene-*co*-4-vinylbenzene phosphonic acid	Styrene-*co*-4-vinylbenzene phosphonic acid diethyl ester	Single T_g	Both I and II had 7.5 or 13.3 mol% phosphorus moiety	1250
Styrene-*co*-4-vinylbenzoic acid, K-neutralized	5,7-Dodecadiyne-1,12-dicarboxylic acid, K-neutralized	Single T_g	I had 26 mol% acid group	990
Styrene-*co*-4-vinylbenzoic acid, triethylammonium ionomer	5,7-Dodecadiyne-1,12-dicarboxylic acid, triethylammonium ionomer	Single T_g; FTIR	I had 26 mol% acid group	990,991
Styrene-*co*-4-vinylphenyl-dimethylsilanol	*n*-Butyl methacrylate	Single T_g; FTIR	I had 9–34 mol% silanol group	1112,1114
	N-Vinyl-2-pyrrolidone	Single T_g; FTIR	I had ≥4 mol% silanol group; formed complex when II had ≥34 mol% silanol group	1113
Styrene-*co*-*p*-vinylphenol	Bis[2-[2-(2-methoxyethoxy) ethoxy]ethyl] itaconate	Single T_g; FTIR	II had 22 mol% vinylphenol	1086
	n-Butyl methacrylate	Transparency; FTIR; fluorescence study	I had 8, 25, 43 or 75 wt.% vinylphenol	103,876
	Caprolactone	Single T_g	I had 10–20.4 wt.% vinylphenol	905,1206
	N,*N*-Dimethylacrylamide	Transparency; FTIR; single T_g; NMR	I had 22, 42 or 82 mol% vinylphenol	487,1064
	Ethyl methacrylate	Transparency; fluorescence study	I had >0.93 mol% vinylphenol	103
	n-Hexyl methacrylate	FTIR; LS	I had 8, 25 or 43 wt.% vinylphenol	876,922
	Methyl methacrylate	Single T_g; transparency; fluorescence study; FTIR; NMR	I had >0.93 mol% vinylphenol; II was atactic, isotactic or syndiotactic	103,487,1055
	Vinyl butyl ether	FTIR	I had 48 wt.% vinylphenol	734
	4-Vinylpyridine	Single T_g	I had 50 mol% vinylphenol	832
Styrene-*co*-4-vinylpyridine	Isoprene, sulfonated	Single T_g; transparency	II had 5–10% substituted and partly cyclized; immiscible when II had 2% substituted	210,896
N,*N*′-Sulfo-*p*-phenylene terephthalamide	Vinyl alcohol	Single T_g	–	972
	4-Vinylpyridine	Single T_g	–	972
	N-Vinylpyrrolidone	NMR	–	972
Sulfone of hexafluorobisphenol-A	Methyl methacrylate	Single T_g	I had $M_w = 27$ kg/mol and II had $M_w = 1.21$ kg/mol; blends of polymers of higher MW showed LCST	931
Sulfone of tetramethylbisphenol-A	Acrylonitrile-*co*-α-methylstyrene	Single T_g	II had 9–19 wt.% AN when I had $M_w =$ 4.8 kg/mol; II had 16–19 wt.% AN when I had $M_w = 12.4$ kg/mol	908,931
	Acrylonitrile-*co*-styrene	Single T_g	II had 11–25 wt.% AN when I had $M_w = 4.8$ kg/mol; II had 13–20 wt.%	931

TABLE 1. *cont'd*

Polymer I of	Polymer II of	Method	Comments	Refs.
			AN when I had $M_w = 12.4$ kg/mol	
	Maleic anhydride-*co*-styrene	Single T_g	II had 17 or 18 wt.% maleic anhydride when I had $M_w = 4.8$ kg/mol	931
Tetrafluoroethylene, sulfonated	Ethyl acrylate-*co*-4-vinylpyridine	Single T_g	I had equivalent weight of 1.155 kg/mol	591
Tetrafluoroethylene-*alt*-vinyl alcohol	Alkyl methacrylate	Single T_g; FTIR	II had an alkyl group of methyl or ethyl (2 miscible blend systems)	961
	Methyl acrylate	Single T_g; FTIR	–	961
	Vinyl acetate	Single T_g; FTIR	–	961
Tetrahydrofurfuryl methacrylate	Allyl alcohol-*co*-styrene	Transparency	II had 5.4–6.0% OH	253
	Epichlorohydrin	Single T_g; transparency	–	117
	Hydroxyether of bisphenol-A (phenoxy)	Single T_g; transparency	–	253
	Vinyl chloride	Single T_g; transparency	–	281
	Vinyl chloride-*co*-vinylidene chloride	Single T_g	II had 88% vinylidene chloride	117
Tetrahydropyranyl-2-methyl methacrylate	Allyl alcohol-*co*-styrene	Transparency	II had 5.4–6.0 wt.% OH	118
	Epichlorohydrin	Single T_g; transparency	–	117
	Hydroxyether of bisphenol-A (phenoxy)	Single T_g; transparency	–	118
	Vinyl chloride	Single T_g; transparency	–	117
	Vinyl chloride-*co*-vinylidene chloride	Single T_g	II had 88% vinylidene chloride	117
	p-Vinylphenol	Single T_g; transparency	–	118
2,2,2-Trichloroethyl methacrylate	Alkyl methacrylate	Single T_g; transparency	II had an alkyl group of methyl, ethyl, *n*-propyl, isopropyl, cyclohexyl or tetrahydrofurfuryl (6 miscible blend systems)	1110
3,3,5-Trimethyl cyclohexyl methacrylate	3,3,5-Trimethyl-cyclohexyl acrylate	Single T_g; transparency	–	765
Trifluoroethylene	Vinylidene fluoride	Single T_g	Semicrystalline	252
Trimethylene adipate	Vinyl chloride	Single T_g; transparency	When $\geq 75\%$ II	872
Urethane	Carbonate of bisphenol-A	Single T_g	I was based on polycarbonate diols and/or polypropylene glycol; miscible when blend had 10–20 wt.% I	997
	Ethylene glycol	FTIR	I was made from a mixture of 2,4- and 2,6-tolyldiisocyanate and 1,4-butanediol	141,347
	Ethylene-*co*-methyl acrylate	Single T_g; FTIR	I was Estane 58311; II had 21 wt.% methyl acrylate	1181
	Ethylene glycol-*co*-propylene glycol	Single T_g; FTIR	I was made from a mixture of 2,4- and 2,6-tolyldiisocyanate and 1,4-butanediol; II had 70 wt.% ethylene glycol	145
	Methacrylic acid-*co*-styrene	Single T_g	I had polyether segment with MW = 1.0 or 2.0 kg/mol; II had 10.5% methacrylic acid, Li-neutralized	707
	Urethane	Single T_g	I and II were separate polymers; I was 4,4′-diisocyanate diphenyl methane (MDI)/dipropylene glycol = 9/10 mol ratio; II was poly G55–56 polyoxyethylene-*co*-oxypropylene, 45% ethylene oxide, MW = 2.0 kg/mol/ MDI/1/1	521
	Vinyl chloride	Single T_g	Blend had ≤ 30 wt.% I	1029
	N-vinylpyrrolidone	Single T_g for II with hard segments of I; soft segment T_gs also observed; clear films	I was segmented, made from methylene bis(4-phenyl isocyanate) and poly-(ethylene glycol) and *cis*-2-butene-1,4-diol and butane-1,4-diol	206
Urethane, functionalized	Acrylic acid-*co*-styrene	Single loss peak; microscopy	I had tertiary amine group; II had 15 or 30 mol% acrylic acid; linear blend of I and II or interpenetrating polymer network of I and II	346
	2-Methyl-5-vinylpyridine-*co*-styrene	Single T_g	I carried pendant carboxylated groups neutralized by ammonium ion	706

TABLE 1. *cont'd*

Polymer I of	Polymer II of	Method	Comments	Refs.
Valerolactone	Vinyl acetate-*co*-vinylidene chloride	Single T_g	Semicrystalline; II was Saran C ($\geq$ 80% vinylidene chloride)	31
	Vinyl bromide	Single T_g	–	150
	Vinyl chloride	Single T_g	Semicrystalline when $\geq 50\%$ I	32,34,35
Vinyl acetate	2-Bromoethyl methacrylate	Single T_g; transparency	Miscible when cast from methyl ethyl ketone; immiscible when cast from tetrahydrofuran	610
	Chloroalkyl methacrylate	Single T_g; transparency	II had chloromethyl or 2-chloroethyl group (2 blend systems)	610
	Hexafluoroacetone-*co*-vinylidene fluoride	Single T_g	II had 8.9 mol% hexafluoroacetone	748,1073
	Maleic anhydride-*co*-styrene hydrolyzed	Single T_g	1.8–43% hydrolyzed	67
	Vinyl nitrate	Single T_g; phase contrast microscopy	–	12
	Vinylidene fluoride	Single T_g	Semicrystalline	53,57
Vinyl acetate-*co*-vinyl chloride	*n*-Butyl methacrylate-*co*-isobutyl methacrylate	Single T_g	Miscibility range depended on compositions of I and II; I had ≥ 81 wt.% vinyl chloride	748
	Hexyl acrylate-*co*-methyl acrylate	Single T_g	I had 5–23.7 vol% vinyl acetate; II had 15–88 vol% hexyl acrylate; miscibility depended on compositions of I and II	379
	n-Butyl methacrylate	Single T_g	I had 5.9–15.1 wt.% vinyl acetate	497
Vinyl alcohol	Ethylene imine	Single T_g	Semicrystalline	1024
Vinyl alcohol	Methacrylic acid	NMR	–	1255,1256,1257
Vinyl alkanoate	Vinyl alkanoate	Single T_g; microscopy	The alkanoate was butyrate, caprate, caproate, caprylate or laurate (5 miscible blend systems)	925
Vinyl butyral	*N*-Vinylpyrrolidone	Single T_g; transparency	$\leq 50\%$ II	209
	Urethane elastomer	Single T_g	II from methylene bisdiphenyl diurethane and polytetramethylene ether glycol; miscible with hard segment	762
Vinyl chloride	Acetonyl methacrylate	Single T_g; transparency	–	123
	Acrylic acid-*co*-carbitylacrylate-*co*-α-methylstyrene-*co*-styrene	Single T_g	II was an oligomer with $M_n = 1.07$ and $M_w = 3.32$ kg/mol	683
	Acrylonitrile-*co*-*n*-butyl acrylate	Optical microscopy	II had 53, 67 or 84 mol% butyl acrylate	655
	Alkyl acrylate	Single T_g	II had pentyl or propyl group (2 blend systems)	851
	Alkyl methacrylate	Single T_g	II had cyclohexyl or isopropyl group (2 blend systems)	319
	Butadiene, epoxidized	Single T_g	II had 50 mol% epoxidation	546
	Butadiene-*co*-styrene, epoxidized	Single T_g	II had 45 wt.% styrene; epoxidation > 40 mol%	544
	Butyl acrylate-*co*-ethyl acrylate	Single T_g	II had 22.9, 43.5 or 52.8% butyl acrylate	851
	Butyl acrylate-*co*-hexyl acrylate	Single T_g	II had 47.8% butyl acrylate	851
	Butyl acrylate-*co*-methyl acrylate	Single T_g	II had 44.6% butyl acrylate	851
	Butyl methacrylate-*co*-methyl methacrylate	Single T_g	II had 30 or 70% methyl methacrylate	880
	Caprolactone-*co*-L-lactide	Single T_g	II had ≤ 40 wt.% lactide	831
	Caprolactone-*co*-lignin	Single T_g; microscopy	II was a 7-armed starlike polymer containing 20 wt.% lignin derivative	984
	Caprolactone-*co*-methylcaprolactone	Single T_g	Whatever composition of II	831
	2,2-Dimethyl-1,3-propylene sebacate	Single T_g; transparency	–	611
	Ethyl acrylate-*co*-hexyl acrylate	Single T_g	II had 41.7 or 43.2% ethyl acrylate	851
	Ethyl acrylate-*co*-methyl methacrylate	Single T_g	II had 10% ethyl acrylate	875
	Ethylene-*co*-vinyl acetate	Permittivity measurements	II had 70% vinyl acetate; composition dependent; miscible when blend contained $\geq 25\%$ II	678
	Methyl acrylate-*co*-hexyl acrylate	Single T_g	II had 9.7% methyl acrylate	851
	Methyl methacrylate-*b*-styrene	–	No gross phase separation when I had $M_n = 43$ kg/mol; PMMA and PS block had the same $M_n = 40$ kg/mol in II	376

TABLE 1. *cont'd*

Polymer I of	Polymer II of	Method	Comments	Refs.
	Nitrile rubber, carboxylated	Single T_g	II was Krynac-221	1170
	Pentyl acrylate-*co*-propyl acrylate	Single T_g	II had 48.1% propyl acrylate	851
	Vinyl acetate	Single T_g	Ref. 59 stated miscible when cast from methyl ethyl ketone and immiscible when cast from tetrahydrofuran; Ref. 183 stated blends cast from both THF and MEK were immiscible	59,183
Vinyl chloride, chlorinated	Alkyl methacrylate	Single T_g; transparency	I had 65 or 68 wt.% Cl; II had *n*-butyl, cyclohexyl, ethyl, *n*-hexyl, *n*-propyl or isopropyl group (6 blend systems)	319,812
	Butadiene, epoxidized	Single T_g	II had 20 or 43 mol% epoxidation	779
	Butadiene-*co*-acrylonitrile	Single T_g	Depended on Cl-content and acrylonitrile content	96,152,355,356
	Ethylene terephthalate	Single T_g	Probably semicrystalline	36
	Hexamethylene sebacate	Single T_g	I had 67.2 wt.% Cl; semicrystalline when ≥ 50 wt.% II	54
	Hexamethylene terephthalate	Single T_g	Semicrystalline	36
	Maleic anhydride-*ran*-styrene	Single T_g	I was Goodrich CPVC 3010; II had 86% styrene	68,69
	α-Methyl-α-*n*-propyl-β-propiolactone	Single T_g	I had 67.2 wt.% Cl	54
	Urethane	Single T_g	I had 67 wt.% Cl; II had a soft poly (tetramethylene adipate) segment capped with 2-hydroxyethyl acrylate	246
	Valerolactone	Single T_g	I had 67.2 wt.% Cl	54
Vinyl chloride-*co*-vinylidene chloride	Alkyl methacrylate	Single T_g	I had 12% vinyl chloride; II had phenyl or isopropyl group (2 blend systems)	409
	Butylene adipate	Single T_g	I had 13.5 wt.% vinyl chloride; semicrystalline	873
	Butylene sebacate	Single T_g	I had 13.5 wt.% vinyl chloride; semicrystalline	873
	Dodecamethylene adipate	Single T_g	I had 13.5 wt.% vinyl chloride; semicrystalline	873
	Dodecamethylene decamethylene dicarboxylate	Single T_g	I had 13.5 wt.% vinyl chloride; semicrystalline	873
	Dodecamethylene dodecamethylene dicarboxylate	Single T_g	I had 13.5 wt.% vinyl chloride; semicrystalline	873
	Hexadecamethylene dodecamethylene dicarboxylate	Single T_g	I had 13.5 wt.% vinyl chloride; semicrystalline	873
	Hexamethylene sebacate	Single T_g	I had 13.5 wt.% vinyl chloride; semicrystalline	873
Vinyl fluoride	Vinylidene fluoride	Single T_g	Semicrystalline; later work found the blends immiscible (Ref. 298)	252,298
Vinyl *p*-methoxycinnamate	*p*-Chloro-(3-ethenoxypropyl) cinnamate	Single T_g	–	515
	Vinyl *p*-chlorocinnamate	Single T_g	–	515
	Vinyl cinnamate	Single T_g	–	515
Vinyl *p*-methylcinnamate	*p*-Chloro-(3-ethenoxypropyl) cinnamate	Single T_g	–	515
	p-Cyano-(3-ethenoxypropyl) cinnamate	Single T_g	–	515
	3-Ethyoxypropyl cinnamate	Single T_g	–	515
	Vinyl *p*-chlorocinnamate	Single T_g	–	515
	Vinyl cinnamate	Single T_g	–	515
Vinyl methyl ether	Acrylonitrile-*co*-styrene	Single T_g	II had < 10-11% acrylonitrile	576
	Alkyl acrylate	Single T_g	II had an alkyl group of ethyl, *n*-propyl or *n*-butyl (3 miscible blend systems)	941
	2-Chlorostyrene	Single T_g; FTIR; SAXS	–	1203
	Epichlorohydrin	NMR, dielectric spectroscopy	–	911,1129
	Maleic anhydride-*co*-styrene	Single T_g	II had 15% maleic anhydride	576
	Methyl methacrylate-*co*-styrene	Single T_g	II had < 60 mol% methyl methacrylate	108,321
	α-Methylstyrene	Light scattering	–	318
	α-Methylstyrene-*co*-4-(2-hydroxyethyl)-α-methylstyrene	Single T_g	II had 6–89 mol% α-methylstyrene	170

TABLE 1. *cont'd*

Polymer I of	Polymer II of	Method	Comments	Refs.
	α-Methylstyrene-*co*-4-(1,1,1-trifluoro-2-hydroxyethyl)-α-methylstyrene	Single T_g	II had 0–96 mol% α-methylstyrene	170
	α-Methylstyrene-*co*-styrene	Light scattering	II had 77.5 or 88 wt.% styrene	318
	m-Methylstyrene-*co*-styrene	FTIR; light scattering	II had 76.5 or 87.5 wt.% styrene	1028
	o-Methylstyrene-*co*-styrene	FTIR; light scattering	II had 76.2 or 86.8 wt.% styrene	1028
	p-Methylstyrene-*co*-styrene	Light scattering	II had ≥ 61 mol% styrene	318,1016
	Nitrostyrene-*co*-styrene	Single T_g	II had ≤ 25.6 mol% nitrostyrene	158,166,192
	Styrene-*co*-1-vinylnaphthalene	Light scattering	II had 17.4, 23, 50 or 80 wt.% styrene; depended on composition of blend	381,406
	Styrene-*co*-2-vinylnapthalene	Single T_g; FTIR; light scattering	II had 19.2, 51 or 84 wt.% styrene	318,1175
	Vinyl alkanoate	Single T_g; IGC	The alkanoate was butyrate or propionate (2 miscible blend systems)	988
	1-Vinylnaphthalene	Single T_g; FTIR	II had $M_n = 5.4$ kg/mol; blend contained 65–85 wt.% II	407
	Vinylidene fluoride	Single T_g; transparent melt	Semicrystalline	58
Vinyl methyl ketone	Vinylidene fluoride	Single T_g; transparent melt	Semicrystalline	58
p-Vinylphenol	Acetonyl methacrylate	Single T_g; transparency	–	118
	4-Acetoxystyrene	Single T_g; FTIR	–	340
	Amide	Single T_g	Polymer II was nylon 6, nylon 6,6 or nylon 11 (3 miscible systems); semicrystalline	1088
	Butyl acrylate-*co*-*t*-butyl acrylate	Single T_g	II had 64 mol% butyl acrylate	897
	Butylene adipate	Single T_g; FTIR; NMR	Semicrystalline	667,919,1088,1089
	Butylene terephthalate	Single T_g; FTIR	Semicrystalline	1088,1089
	Caprolactone	Single T_g; FTIR; IGC	Semicrystalline	143,667,1088,1096
	Cellulose tripropionate	Single T_g	–	1088
	Copolyester	Single T_g; FTIR	II was five different copolyesters	1089
	Dialkyl itaconate	Single T_g; FTIR	II had a dialkyl group or methyl, ethyl, bis[2-[2-(2-methoxyethoxy)ethoxy] ethyl or bis[2-(2-methoxyethoxy)ethyl (4 miscible blend systems)	1034,1086
	N,N-dimethylacrylamide	Single T_g	Formed complexes in dioxane or acetone	487,795,857, 1088,1089
	2,2-Dimethylpropylene terephthalate	Single T_g; FTIR	–	1088,1089
	Ethyl acrylate	FTIR	–	143
	γ-Ethyl L-glutamate	FTIR; microscopy	–	639,902
	Ethyl methacrylate	Single T_g; FTIR	–	146,282,733,1164
	Ethyl methacrylate-*co*-methyl methacrylate	Single T_g; FTIR	II had 30, 60 or 70 wt.% MMA	1162,1164
	Ethylene adipate	Single T_g; NMR	Semicrystalline	667,919,1089
	Ethylene 2,6-naphthalene dicarboxylate	Single T_g; FTIR	–	1088,1089
	Ethylene succinate	Single T_g	Semicrystalline	919
	Ethylene terephthalate	Single T_g; FTIR	Semicrystalline	1089
	Ethylene-*co*-vinyl acetate	Single T_g; FTIR	II had 70% vinyl acetate	143,144,588
	Hexamethylene sebacate	Single T_g	Semicrystalline	667
	n-Hexyl methacrylate-*co*-methyl methacrylate	Single T_g; FTIR	II had 20, 38 or 48 wt.% *n*-hexyl methacrylate	958
	Hexylene-*m*-xylene dicarboxamide	Single T_g	–	1088
	2-(2-Methoxyethoxy)ethyl methacrylate	Single T_g; FTIR	–	1086
	γ-Methyl L-glutamate	FTIR; microscopy	–	639,902
	Methyl acrylate	FTIR; NMR	–	143,889,894,1195,1224
	Methyl methacrylate	Single T_g; FTIR; NMR	–	146,282,487,733,1164,1224
	n-Propyl acrylate	FTIR	–	143,641
	n-Propyl methacrylate	FTIR; single T_g	–	146,282,733
	Isopropyl methacrylate	Single T_g	–	280
	Styrene-*co*-4-vinylbenzenephosphonic acid diethyl ester	Single T_g; FTIR; NMR	II had >7.5 mol% phosphorus groups	1249
	Styrene-*co*-4-vinylpyridine	Single T_g	II had 50 mol% 4-vinylpyridine	832
	Styrene-*co*-2-vinylpyridine	Single T_g; FTIR	Formed complexes in ethanol; II had 70 mol% 2-vinylpyridine	976
	Tetrahydrofuran	FTIR; transparency	–	734

TABLE 1. *cont'd*

Polymer I of	Polymer II of	Method	Comments	Refs.
	Tetrahydrofurfuryl methacrylate	Single T_g	–	282
	2,2,5-Trimethylene terephthalamide	Single T_g	–	1088
	Vinyl acetate	Single T_g; FTIR	–	143,144,588
	Vinyl methyl ether	Single T_g; FTIR	–	1150
	Vinylpyridine	Single T_g; FTIR	Formed complexes; II was 2- or 4-vinylpyridine (2 miscible systems)	832,976
	N-vinylpyrrolidone	Single T_g	Formed complexes from methanol	857
Vinyl propionate	Ethyl acrylate	Single T_g; transparency; IGC	–	60,61
N-vinylpyrrolidone	Alkyl methacrylate	Single T_g	II had an alkyl group or methyl or ethyl; miscible when cast from chloroform (Ref. 1141); immiscible when cast from DMF (Ref. 607)	607,1141
	Allyl alcohol-*co*-styrene	Single T_g; transparency	II had 5.4–6.0 or 7.3–8.0 wt.% OH	284,977
	Aramide	Single T_g; transparency	Polymer II was five different types of aramides	947
	Benzimidazole	Single T_g; transparency	–	947
	n-Butyl methacrylate-*co*-2-hydroxyethyl methacrylate	Single T_g; transparency	II had $\geq$20.9 mol% 2-hydroxyethyl methacrylate	501
	Haloalkyl methacrylate	Single T_g; FTIR	II had a haloalkyl group of chloromethyl, 2-chloroethyl, 3-chloropropyl, 2-bromoethyl or 2-iodoethyl (5 miscible blend systems)	607,1109,1141
	Copolyamide	Single T_g	II had 1/1/1 = caprolactam/hexamethylene adipamide/hexamethylene sebacamide structural unit	315
	Dialkyl itaconate	Single T_g	II had an dialkyl group of dimethyl, di-2-chloroethyl or di-3-chloropropyl (3 miscible blend systems)	1141
	Epoxy resin	Single T_g; FTIR	–	370
	Ethersulfone	Single T_g	–	307
	Ethylene glycol	Single T_g	I had MW = 360 kg/mol; II had MW = 0.3 kg/mol	780
	Epichlorohydrin	Single T_g	–	300
	Ethyl methacrylate-*co*-2-hydroxyethyl methacrylate	Single T_g; transparency	II had $\geq$7.5 mol% 2-hydroxyethyl methacrylate	265
	2-Hydroxyethyl methacrylate	Single T_g; transparency	–	284
	2-Hydroxyethyl methacrylate-*co*-methyl methacrylate	Single T_g; transparency	II had $\geq$1.9 mol% 2-hydroxyethyl methacrylate	501
	2-Hydroxypropyl methacrylate	Single T_g; transparency	–	284,977
	Methacrylic acid	NMR	Formed complexes	1128
	Monoalkyl itaconate	FTIR	II had an alkyl group of benzyl or ethyl (2 blend systems); formed complexes	95,938
	Sulfone	Single T_g; transparency	–	255
	Sulfone, carboxylated	Single T_g; transparency	II had degree of carboxylation 0.43–1.93	255
	Vinyl alcohol	Single T_g; NMR	Semicrystalline	624,659,805,856,890,998
	Vinyl alcohol-*co*-vinyl acetate	Single T_g	II had $\geq$70% vinyl alcohol	207
	Vinyl chloride	Single T_g	–	300
	Vinyl formal	Single T_g: FTIR	–	349,1044
Vinylidene fluoride	Acetonyl methacrylate	Single T_g	Semicrystalline	122
	N,*N*-Dimethylacrylamide	Single T_g	Semicrystalline	242
	Ethyl methacrylate-*co*-methyl methacrylate	T_m-depression	II had 16–80 wt.% methyl methacrylate	283
	Methacrylic acid-*co*-methyl methacrylate	Single T_g; T_m-depression	Semicrystalline; II had 2.2–9.5 mol% methacrylic acid	1094
	Methyl methacrylate-*co*-styrene	Single T_g	II had < 13 vol% styrene	388
	N-Methyl-*N*-vinylacetamide	Single T_g	Semicrystalline	242
	Methoxymethyl methacrylate	Single T_g	Semicrystalline	267
	Pivalolactone	T_m-depression	Semicrystalline	1038
	N-Vinylpyrrolidone	Single T_g	Semicrystalline	17,94,241,408
Vinylpyridine	Hydroxyalkyl methacrylate	Single T_g; FTIR	I was 2- or 4-vinylpyridine; II had an alkyl group of 2-hydroxyethyl or 3-hydroxypropyl (4 miscible systems)	937

TABLE 1. *cont'd*

Polymer I of	Polymer II of	Method	Comments	Refs.
	Monoalkyl itaconate	Single T_g; FTIR	I was 2- or 4-vinylpyridine; II had an alkyl group or methyl or ethyl (4 miscible systems); formed complexes	939,1014, 1212
	Vinyl acetate-*co*-vinyl alcohol	Single T_g; FTIR	I was 2- or 4-vinylpyridine (2 miscible systems); II had 29–88 mol% vinyl alcohol	934,935,991
	Vinyl butyral	SALS	I was 2- or 4-vinylpyridine (2 miscible systems)	1003
2-Vinylpyridine	Aramide	Single T_g; FTIR	II was made from hexamethylene-diamine and a mixture of tereph-thaloyl and isophthaloyl dichlorides	767
4-Vinylpyridine	Methylocellulose	Single T_g; NMR	–	559
	Sulfone, carboxylated	Single T_g; transparency	II had degree of carboxylation 0.43–1.93	256
	p-Phenylene terephthalamide	Transparency; microscopy	–	329
2,3-Xylenyl methacrylate	2,6-Xylenyl methacrylate	Single T_g	–	1158

TABLE 2. POLYMER PAIRS CONTAINING ONE MONOMER IN COMMON, MISCIBLE IN THE AMORPHOUS STATE AT ROOM TEMPERATURE

Polymer I of	Polymer II of	Method	Comments	Refs.
Acrylic acid-*co*-styrene	Methyl methacrylate-*co*-styrene	Single T_g	Miscibility depended on compositions of I and II	72
Acrylonitrile-*co*-butadiene	Acrylonitrile-*co*-butadiene	Single T_g; clear films; electron microscopy	Difference in composition between I and II ≤22% acrylonitrile	19,47,101,106, 149,390,452
	Acrylonitrile-*co*-styrene	Single T_g	–	162
	Acrylonitrile-*co*-vinylidene chloride	Single T_g	I had 23.6–49.6 vol% AN; II had 19 wt.% AN	966
Styrene-*co*-maleic anhydride--*co*-acrylonitrile	Acrylonitrile-*co*-styrene	Single T_g	Miscibility depended on compositions of I and II	965
	Maleic anhydride-*co*-styrene	Single T_g	Miscibility depended on compositions of I and II	965
Acrylonitrile-*co*-methyl methacrylate	Acrylonitrile-*co*-*N*-phenylitaconimide	Single T_g	–	168
	Itaconic anhydride-*co*-methyl methacrylate	Single T_g	Miscibility depended on compositions of I and II	920
	Methyl methacrylate-*co*-*N*-phenylitaconimide	Single T_g	–	168
Acrylonitrile-*co*-methyl methacrylate-*co*-α-methylstyrene	Methyl methacrylate	Single T_g	I had 20/20/60 = acrylonitrile/methyl methacrylate/α-methylstyrene	633
Acrylonitrile-*co*-methyl methacrylate-*co*-styrene	Acrylonitrile-*co*-styrene	Light scattering	–	358
	Methyl methacrylate	Light scattering	–	358
Acrylonitrile-*co*-α-methylstyrene	Acrylonitrile-*co*-methyl methacrylate	Single T_g	–	152
	Acrylonitrile-*co*-styrene	Single T_g	I had 32.3 wt.% acrylonitrile; II had 27 wt.% acrylonitrile	155,684
Acrylonitrile-*co*-α-methylstyrene-*co*-styrene	Acrylonitrile-*co*-α-methyl styrene-*co*-styrene	Clear films	Difference in composition between I and II < 12% acrylonitrile	769
Acrylonitrile-*co*-styrene	Acrylic acid-*co*-styrene	Single T_g	–	380
	Acrylonitrile-*co*-benzyl methacrylate	Single T_g	–	1180
	Acrylonitrile-*co*-fumaronitrile-*co*-styrene	Single T_g	I had 32–40 wt.% AN; II had 11–17 wt.% fumaronitrile	1222
	Acrylonitrile-*co*-methyl methacrylate	Single T_g	–	164,620
	Acrylonitrile-*co*-*N*-phenylitaconimide	Single T_g	–	168
	Acrylonitrile-*co*-styrene	Single T_g; no visible phase separation	Difference in composition between I and II < 3.5% acrylonitrile	485,582
	p-(2-Hydroxy-hexafluoroisopropyl)-styrene-*co*-styrene	Single T_g; clear film	I had 70% styrene; II had 90.3% styrene	571,646
	Maleic anhydride-*co*-styrene	Single T_g	I had 44.4–94.6 wt.% styrene; II had 50–91.5 wt.% styrene	25,462,554, 745,1008

TABLE 2. *cont'd*

Polymer I of	Polymer II of	Method	Comments	Refs.
	N-phenylitaconimide-*co*-styrene	Single T_g	–	164
	N-phenylmaleimide-*co*-styrene	Single T_g	–	25,26
3-Bromo-2,6-dimethyl-1,4-phenylene ether	3-Bromo-2,6-dimethyl-1,4-phenylene ether-*co*-2,6-dimethyl-1,4-phenylene ether	Single T_g; microscopy	II had $\geq$48 mol% 3-bromo-2,6-dimethyl-1,4-phenylene oxide	402
3-Bromo-2,6-dimethyl-1,4-phenylene ether-*co*-2,6-dimethyl-1,4-phenylene ether	2,6-dimethyl-1,4-phenylene ether	Single T_g; microscopy	I had $\geq$62 mol% 2,6-dimethyl-1,4-phenylene ether	402
p-Bromostyrene-*co*-styrene	Styrene	Single T_g	I had $\geq$90 mol% styrene	402,785
Butadiene	Butadiene	Single T_g	Semicrystalline; I was SKD (87% *cis*-1,4) and II was SKBM (Ref. 251); I had 50% vinyl-1,2, 35% *cis*-1,4 and 15% *trans*-1,4, and II had 98% *cis*-1,4 (Ref. 736); I had 50% vinyl-1,2, 35% *cis*-1,4 and 15% *trans*-1,4, and II had 55% *trans*-1,4, 35% *cis*-1,4 and 10% vinyl-1,2 (Ref. 736)	251,736
	Butadiene-*co*-styrene	Single T_g	II had >70% butadiene; immiscible when II had <60% butadiene	92,149,182, 237,238,520,548, 549,737,770,771, 787,882
Butadiene-*co*-styrene	Butadiene-*co*-styrene	Single T_g; microscopy	Difference in composition between I and II <20% styrene; two T_g's when composition difference >20%	182,519,520, 455,757,771
	Styrene	Single dynamic mechanical loss peak	I had 25% styrene; II had $M_w \leq 917$; $\leq$50% II; two loss peaks when 75% II	138,139
Butyl acrylate-*co*-butyl methacrylate	Butyl acrylate-*co*-butyl methacrylate	Clear films	Difference in composition between I and II 25% butyl acrylate; immiscible when composition difference 50% butyl acrylate	453
Butyl acrylate-*co*-*N*-hydroxyethylcarbozolyl acrylate	Butyl acrylate-*co*-β-hydroxyethyl-3,5-dinitrobenzoyl acrylate	Single T_g	I had 6 or 48 mol% electron donating carbozoyl groups; II had 10 or 63 mol% electron withdrawing dinitrobenzoyl groups	723
Butyl acrylate-*co*-ethyl acrylate	Butyl acrylate-co-ethyl acrylate	Clear films	Difference in composition between I and II 25% ethyl acrylate; immiscible when composition difference 50% ethyl acrylate	453
	Ethyl acrylate	Clear films	I had 75% ethyl acrylate; immiscible when I had $\leq$50% ethyl acrylate	453
Butyl acrylate-*co*-methyl methacrylate	Butyl acrylate-*co*-methyl methacrylate	Single T_g; clear films	Difference in composition between I and II $\leq$10% methyl methacrylate	447,448
n-Butyl methacrylate	*n*-Butyl methacrylate-*co*-styrene	Single T_g; clear films	II had $\geq$90 wt.% *n*-butyl methacrylate	238
n-Butyl methacrylate-*co*-*p*-chlorostyrene	*n*-Butyl methacrylate-*co*-*p*-chlorostyrene	Single T_g; microscopy	–	76
n-Butyl methacrylate-*co*-*N*-hydroxyethylcarbazoyl acrylate	*n*-Butyl methacrylate-*co*-β-hydroxyethyl-3,5-dinitrobenzoyl acrylate	Single T_g	I had 9 mol% carbazoyl groups; II had 9 mol% dinitrobenzoyl groups	723
Butyl methacrylate-*co*-methyl methacrylate	Butyl methacrylate-*co*-methyl methacrylate	Clear films	Difference in composition between I and II $\leq$20–30% butyl methacrylate, depending on compositions of I and II	76,447
n-Butyl methacrylate-*co*-styrene	*n*-Butyl methacrylate-*co*-styrene	Single T_g; microscopy		76
	Styrene	Single T_g; clear films	I had $\geq$90 wt.% styrene	239
Caprolactam-*co*-caprolactone	Caprolactone-*co*-laurolactam	Single T_g	I and II had various compositions	1126
Caprolactam-*co*-caprolactone-*co*-laurolactam	Caprolactam-*co*-laurolactam	Single T_g	I and II had various compositions	992
2,6-Dimethyl-1,4-phenylene ether, sulfonylated	2,6-Dimethyl-1,4-phenylene ether, sulfonylated	Single T_g	Difference in degree of sulfonylation between I and II in the range of 20–26 wt.%	410
Dimethylsiloxane, functionalized	Dimethylsiloxane, functionalized	Single T_g	I had 4–15 mol% electron-donating carbazoyl or *N*-methylaniline groups; II had 4–15 mol% electron-accepting	723

References page VI-461

TABLE 2. *cont'd*

Polymer I of	Polymer II of	Method	Comments	Refs.
			dinitrobenzoyl groups; donor/ acceptor = 1/1	
Epichlorohydrin	Epichlorohydrin-*co*-ethylene glycol	Single T_g	I was Hydrin 100; II was Hydrin 200	373
Ethyl acrylate-*co*-ethyl methacrylate	Ethyl acrylate-*co*-ethyl methacrylate	Clear films	I and II had 25, 50 or 75% ethyl acrylate	453
	Ethyl methacrylate	Clear films	I had 75 wt.% ethyl methacrylate; immiscible when I had $\leq$ 50 wt.% ethyl methacrylate	453
Ethyl acrylate-*co*-methyl methacrylate	Ethyl acrylate-*co*-methyl methacrylate	Clear films	Difference in composition between I and II < 20–27% ethyl acrylate depending on compositions of I and II	447
Ethylene, chlorinated	Ethylene, chlorinated	Single T_g; clear films	Difference in composition between I and II $\leq$ 1.2–13.3 wt.% Cl depending on compositions of I and II	97,98, 636,817
	Ethylene-*co*-methyl acrylate	Single T_g; phase contrast microscopy	Semicrystalline when I had 25 wt.% Cl; I had 25 or 48 wt.% Cl	396
	Ethylene-*co*-vinyl acetate	Single T_g; microscopy	I had 35.4–52.6 wt.% Cl; II had 50–60 wt.% ethylene	849
Ethylene-*co*-vinyl acetate	Ethylene, low density	Single T_g	I:II = 50 : 50	1172
	Ethylene-*co*-vinyl acetate	Single T_g; microscopy	I and II had 7–100 wt.% vinyl acetate	925
	Ethylene-*co*-vinyl alcohol	Single T_g; FTIR	I had 21 mol% vinyl acetate; II had 21 mol% vinyl alcohol	960
	Vinyl acetate-*co*-vinyl chloride	Single T_g	–	745,746
Ethylene-*co*-vinyl chloride	Ethylene-*co*-vinyl chloride	Single T_g	Difference in vinyl chloride or ethylene content of I and II < 15 mol%	70,71
	Vinyl chloride	Single T_g	I had > 80 mol% vinyl chloride	70
Ethylene naphthalene-2,6-dicarboxylate	Ethylene naphthalene-2,6-dicarboxylate-*co*-4-hydroxybenzoate	NMR	II had 20 mol% 4-hydroxybenzoate	1027
Ethyl methacrylate-*co*-methyl methacrylate	Ethyl methacrylate-*co*-methyl methacrylate	Single T_g	–	98
o-Fluorostyrene-*co*-*p*-fluorostyrene	*o*-Fluorostyrene-*co*-*p*-fluorostyrene	Single T_g	I and II had 10 and 23 mol% *p*-fluorostyrene, respectively	1144
o-Fluorostyrene-*co*-styrene	*o*-Fluorostyrene-*co*-styrene	Single T_g	I had 18 or 49% *o*-fluorostyrene; II had 40 or 77% *o*-fluorostyrene	716,1144
	Styrene	Single T_g	I had 18, 40 or 49% *o*-fluorostyrene and II had M_n = 15 kg/mol I had 18% *o*-fluorostyrene and II had M_n = 110 kg/mol	716,1144
p-Fluorostyrene-*co*-styrene	Styrene	Single T_g	I had 8 or 16 mol% *p*-fluorostyrene; II had M_n = 40 or 326 kg/mol	1144
Hydrocarbon polymer, chlorinated	Hydrocarbon polymer, chlorinated	Clear films	One series derived from reduction of polyvinyl chloride and one series derived from chlorination of polyethylene	75
p-Hydroxybenzoic acid-*co*-6-hydroxy-2-naphthoic acid-*co*-terephthalic acid-*co*-hydroquinone	*p*-Hydroxybenzoic acid-*co*-6-hydroxy-2-naphthoic acid	Single T_g; X-ray diffraction	X-ray diffraction showed no significant transesterification occurred in the mixture	92
Hydroxybutyrate	Hydroxybutyrate	Microscopy; SAXS	I was isotactic; II was atactic	903
	Hydroxybutyrate-*co*-hydroxyvalerate	Microscopy; melting behavior	II had 3.8–22.3 mol% hydroxyvalerate	1142,1143
Isoprene	Isoprene-styrene block copolymer	Electron microscopy	I had M_n = 6.5–53.9 kg/mol; II was diblock, triblock or four-arm star copolymer having total M_n = 26–622 kg/mol	378
Maleic anhydride-*co*-styrene	Acrylonitrile-*co*-styrene	Single T_g, transparency, microscopy	I had 15.3 wt.% maleic anhydride; II had 15.0, 19.5 or 25.0 wt.% acrylonitrile	436,555
	Maleic anhydride-*co*-styrene	Single T_g	Miscibility occurred when difference in MA contents between I and II was < 2.5 vol%	1159
	Methyl methacrylate-*co*-styrene	Single T_g	Miscibility depended on compositions of I and II	1008
Maleimide-*co*-styrene	Styrene-*co*-2-vinylpyridine	Single T_g; FTIR	I had 86 wt.% styrene; IH had 30 wt.% styrene	1214

TABLE 2. *cont'd*

Polymer I of	Polymer II of	Method	Comments	Refs.
Methacrylic acid-*co*-methyl methacrylate	Methyl methacrylate-*co*-4-vinylpyridine	Phase diagram	I had 91.48 or 77.7 mol% methyl methacrylate; II had 80.2 mol% methyl methacrylate	198
Methacrylic acid-*co*-styrene	Butyl methacrylate-*co*-methacrylic acid	Single T_g	I and II had 13.7 and 20.2 mol% methacrylic acid, respectively; both were Na-neutralized	1051
	Styrene-*co*-4-vinylpyridine	Phase diagram	I had 89.5 mol% styrene; II had 83.9 mol% styrene	198
Methacrylonitrile-*co*-styrene	Methacrylonitrile-*co*-methyl methacrylate	Single T_g	Miscibility depended on compositions of I and II	970
	Methacrylonitrile-*co*-styrene	Single T_g	Miscibility depended on compositions of I and II	970
[4-(Methacryloyloxy)-butyl]-pentamethyldisiloxane	[4-(Methacryloyloxy)-butyl]-pentamethyldisiloxane-*co*-methyl methacrylate	Single T_g; clear films	II had 67% methyl methacrylate	64
[4-(Methacryloyloxy)-butyl]-pentamethyldisiloxane-*co*-methyl methacrylate	Methyl methacrylate	Single T_g; clear films	I had 67 or 75% methyl methacrylate	64
Methyl acrylate	Methyl acrylate-*co*-vinyl acetate	Clear films	II had 25–75% methyl acrylate	453
Methyl acrylate-*co*-methyl methacrylate	Methyl acrylate-*co*-methyl methacrylate	Clear films	Difference in composition between I and II 28–48% methyl acrylate when I and II had degree of polymerization = 400 and 20–35% methyl acrylate when I and II had degree of polymerization = 3000, depending on compositions of I and II	447
Methyl acrylate-*co*-vinyl acetate	Vinyl acetate	Clear films	I had 25–75% vinyl acetate	453
Methyl methacrylate	Ethyl methacrylate-*co*-methyl methacrylate	Single T_g	I was isotactic; II had $\leq$45% ethyl methacrylate	727
	Methyl methacrylate	Single T_g	I was isotactic; II was sydiotactic	727
	Methyl methacrylate-*alt*-styrene	Single T_g; microscopy	Deuterated blends were miscible; miscibility affected by deuteration of I	1006
Methyl methacrylate-*co*-(*N*-ethylcarbazol-3-yl)methyl methacrylate	Methyl methacrylate-*co*-2-[(3,5-dinitrobenzoyl)oxy]ethyl methacrylate	Single T_g	I and II had similar acceptor or donor content	1160
Methyl methacrylate-*co*-styrene	Acrylonitrile-*co*-styrene	Single T_g	–	164,404
	Maleic anhydride-*co*-styrene	Single T_g	–	404
	Methyl methacrylate-*co*-*N*-phenylitaconimide	Single T_g	–	168
	Methyl methacrylate-*co*-styrene	Single T_g; microscopy	–	76,444
	N-Phenylitaconimide-*co*-styrene	Single T_g	–	168
p-Nitrostyrene-*co*-styrene	*p*-Nitrostyrene-*co*-styrene	Single T_g	–	158
Novolac resin	Novolac resin	Single T_g	I was formaldehyde and 13/17/70 mol% = *p*-*tert*-butyl phenol/*m*-cresol/*o*-cresol; II was formaldehyde and 15/85 mol% = 2-*tert*-butyl phenol/*o*-cresol; I and II had MW 0.8–1.6 kg/mol	221
N-Phenylmaleimide-*co*-styrene	4-Cyanostyrene-*co*-styrene	Single T_g	I had 39 wt.% styrene; II had 58.5–83.1 mol% styrene	187
	2-Cyanostyrene-*co*-4-cyanostyrene-*co*-styrene	Single T_g	II had 23.5 or 22.7 mol% styrene; ratios of 2-cyanostyrene/4-cyano-styrene were 25:75 or 78:22	187
Styrene	Styrene	Single T_g	I had MW = 0.8 kg/mol; II had MW = 8420 kg/mol; I/II = 31.7/68.5	102
	Styrene, iodinated	Transparency	II had degree of iodination of 6 or 15%	261
Styrene-*co*-styrenesulfonic acid	Styrene-*co*-*p*-vinylphenol	Single T_g; FTIR	I had 86 mol% styrene; II had 22 mol% vinylphenol	1086
	Styrene-*co*-4-vinylphenol	FTIR	I had 1.8–9.9 mol% acid; II had 1.9–9.9 mol% pyridine	1190
Styrene-*co*-vinylphenol	Styrene-*co*-vinylphenol	FTIR	–	349
	Vinylphenol	Single T_g; FTIR	I had > 11 mol% OH groups	1247,1088
Sulfone	Sulfone, carboxylated	Single T_g	Degree of carboxylation of II $\leq$1.3	1258
Vinyl acetate-*co*-vinyl chloride	Vinyl chloride	Single T_g; microscopy of fibers	I had 78 or 86 wt.% vinyl chloride	449
	Vinyl chloride, chlorinated	Single T_g	–	745

TABLE 2. *cont'd*

Polymer I of	Polymer II of	Method	Comments	Refs.
Vinyl acetate-*co*-vinyl sterate	Vinyl acetate-*co*-vinyl sterate	Single T_g; microscopy	I and II had 21–98 wt.% vinyl acetate	925
Vinyl chloride	Propylene-*co*-vinyl chloride	Single T_g; microscopy of fibers	II had 89 or 91 wt.% vinyl chloride	449
Vinyl chloride, chlorinated	Vinyl chloride	Single T_g	Up to 61.3 or 65.2% Cl in I with dependence on mol% CCl_2 groups	91,504,505
	Vinyl chloride, chlorinated	Single T_g	Difference in composition between I and II $\leq$3–4% Cl depending on composition of I and II with dependence on number of CCl_2 groups	98,504

TABLE 3. CHEMICALLY DISSIMILAR POLYMER TRIADS (AND TETRADS) MISCIBLE IN THE AMORPHOUS STATE AT ROOM TEMPERATURE

Polymer I of	Polymer II of	Polymer III of (and Polymer IV of)	Method	Comments	Refs.
Acrylic acid-*co*-styrene	Ethylene glycol	Methyl methacrylate	Single T_g	I had 12.2, 20.8 or 33.1 mol% acrylic acid	384
Acrylonitrile-*co*-butadiene	Vinyl chloride	Vinyl chloride-*co*-vinylidene chloride	Single T_g	Semicrystalline; I had 30 or 40 wt.% acrylonitrile; III had 65 wt.% vinylidene chloride	860
Acrylonitrile-*co*-butadiene-*co*-styrene	Carbonate of bisphenol-A	Propylene-*co*-vinyl chloride	Single T_g	I was Blendex 701; II was Merlon M39, M-60; III had 3.2 or 3.8% propylene; I/II/III = 1/1/2; two T_g's when I/II/III = 3/7/10	107
Acrylonitrile-*co*-methyl methacrylate	Acrylonitrile-co-styrene	Maleic anhydride-*co*-styrene	Single T_g	I had 12% acrylonitrile; II had 25% acrylonitrile; III had 25% maleic anhydride	74
	Acrylonitrile-*co*-styrene	Methyl methacrylate-*co*-*N*-phenylitaconimide	Single T_g	I had 68 or 95 vol% MMA; II had 63 or 70 vol% styrene; III had 12 or 45 vol% MMA; three miscible binary pairs; there was an immiscibility loop	967
	Acrylonitrile-*co*-styrene	Methyl methacrylate-*co*-styrene	Single T_g	I had 2.7–7.4 vol% acrylonitrile; II had 14.5–49.5 vol% acrylonitrile; III had 11.2–16.0 vol% styrene	163,165
Acrylonitrile-*co*-α-methylstyrene	Acrylonitrile-*co*-styrene	Vinyl chloride	Single T_g	I had 32.3 wt.% acrylonitrile; II had 27 wt.% acrylonitrile; >25% I	684
	Ethyl methacrylate	Methyl methacrylate	Single T_g	I had 30 wt.% acrylonitrile	290
Acrylonitrile-*co*-*N*-phenylitaconimide	Acrylonitrile-*co*-styrene	*N*-phenylitaconimide-*co*-styrene	Single T_g	I had 6 or 9 vol% acrylonitrile; II had 22, 44 or 65 vol% acrylonitrile; III had 12 or 42 vol% styrene	157
Acrylonitrile-*co*-styrene	Butylene adipate	Carbonate of bisphenol-A	Single T_g	I had 12 or 25% acrylonitrile	738
	Caprolactone	Carbonate of bisphenol-A	Single T_g	–	738
	Caprolactone	Hydroxyether of bisphenol-A (phenoxy resin)	Single T_g	I had 5.7–30 wt.% AN	1209,1052
	Caprolactone	Maleic anhydride-*co*-styrene	Single T_g	I had 15 wt.% AN; III had 14 wt.% maleic anhydride	1210
	Caprolactone	Vinyl chloride	Single T_g	Miscible when I/II/III = 68/16/16	351
	Carbonate of bisphenol-A	Cyclohexane dimethylene succinate	Single T_g	–	738
	Ethyl methacrylate	Maleic anhydride-*co*-styrene	Single T_g	I had 25% acrylonitrile; III had 14–25% acrylonitrile	74
	Ethyl methacrylate	Methyl methacrylate	Single T_g	I had 30 wt.% acrylonitrile; some blends showed LCST	280
	Methyl methacrylate	Vinyl chloride	Single T_g	I had 23 wt.% acrylonitrile	349

TABLE 3. *cont'd*

Polymer I of	Polymer II of	Polymer III of (and Polymer IV of)	Method	Comments	Refs.
n-Amyl methacrylate	*n*-Butyl methacrylate	Vinyl chloride	Single T_g	Blend had >70 wt.% III	1157
	n-Propyl methacrylate	Vinyl chloride	Single T_g	Blend had >70 wt.% III	1157
Arylate	Butylene therphthalate	Hydroxyether of bisphenol-A (phenoxy)	Single T_g	I was Arilef U-100; III >30 wt.%	7,208,366
3-Bromo-2,6-dimethyl-1,4-phenylene ether-*co*-2,6-dimethyl-1,4-phenylene ether	*p*-Bromostyrene-*co*-styrene	2,6-dimethyl-1,4-phenylene ether	Single T_g; microscopy	≤37 mol% brominated monomer in I and in II	402
	p-Bromostyrene-*co*-styrene	Styrene	Single T_g; microscopy	≤16 mol% brominated monomer in I and in II	402
	2,6-Dimethyl-1,4-phenylene ether	Styrene	Single T_g; microscopy	≤45 mol% brominated monomer in I	402
	p-Bromostyrene-*co*-styrene	2,6-Dimethyl-1,4-phenylene ether (polymer IV of styrene)	Single T_g; microscopy	≤26 mol% brominated monomer in I and in II	402
p-Bromostyrene-*co*-styrene	2,6-dimethyl-1,4-phenylene ether	Styrene	Single T_g; microscopy	≤29 mol% *p*-bromostyrene in I	402
Butylene terephthalate	Carbonate of bisphenol-A	Hydroxyether of bisphenol-A (phenoxy)	Single T_g	–	608,681
	Hydroxyether of bisphenol-A (Phenoxy)	Methyl methacrylate	Single T_g, microscopy	Blend had >50 wt.% II	1053
Caprolactone	Carbonate of bisphenol-A	Carbonate of tetramethylbisphenol-A	Single T_g	Miscible at all compositions	1070
	Carbonate of bisphenol-A	Hydroxyether of bisphenol-A (phenoxy)	Single T_g	Generally miscible when >60 wt.% I in blend	125
	Hydroxyether of bisphenol-A (Phenoxy)	Vinyl methyl ether	Single T_g	Miscible at all compositions; all blends showed LCST	303
	Vinyl chloride	Vinyl chloride, chlorinated	Single T_g	II had 67.2 wt.% Cl; generally miscible when I >40% at high II/III ratio and miscible when I >26% at low II/III ratio	20
Carbonate of bisphenol-A	Carbonate of bisphenol chloral	Methyl methacrylate	Single T_g	–	427
	Carbonate of tetra-methylbisphenol-A	Acrylonitrile-*co*-styrene	Single T_g	III had 2.7–19.7 wt.% AN	1068
	Carbonate of tetra-methylbisphenol-A	Methyl methacrylate-*co*-styrene	Single T_g	III had 4.5–58.5 wt.% MMA	1068
	Carbonate of tetra-methylbisphenol-A	Styrene	Single T_g	–	488,1068
Carbonate of tetra-methylbisphenol-A	Methyl methacrylate	Methyl methacrylate-*co*-styrene	Single T_g	–	884
2-Chlorostyrene	Cyclohexyl acrylate	Styrene	Single T_g; light scattering	Three miscible binary pairs; there was an immiscibility loop in the phase diagram	1167
Copolyester	Epoxy	Hydroxyether of bisphenol-A (phenoxy)	Single T_g, microscopy	II/III = 1/1; I was made from 65/30/5 = terephthalate/isophthalate/sebacate and 70/20/10 = ethylene glycol/resorcinal di(β-hydroxy ethyl)ether/poly(tetra-methylene ether)glycol; II was 4/1 by wt. = Araldite 6099/Araldite 6010	2
Epichlorohydrin	Ethylene glycol	Methyl methacrylate	Single T_g	Miscible at all compositions	573
	Methyl methacrylate	Vinyl acetate	Single T_g	Miscible at all compositions; all blends showed LCST	304
Etherimide	Amideimide	Ether ether ketone, sulfonated	Single T_g	I was Ultem 1000; II was Torlon 4000T; III had degree of sulfonation of 0.53 or 1.00	415
	Ether ether ketone	Liquid crystalline polymer	Single T_g	I was Ultem 1000; II was Victrex 450G; III was HX4000	78
Ether urethane	Oxytetramethylene-*co*-oxyditetramethylene-*co*-terephthalic acid	Vinyl chloride	Single T_g	I was Adiprene L-100 and 4,4′-methylene-bis-2-chloro-aniline: I/II/III = 1/1/2; two T_g's when I/II/III = 1/2/1 and 1/1/1	344

TABLE 3. *cont'd*

Polymer I of	Polymer II of	Polymer III of (and Polymer IV of)	Method	Comments	Refs.
Ethyl methacrylate	Methyl methacrylate	*p*-Vinylphenol	Single T_g; FTIR; microscopy	Blend had ≥60 wt.% III	1161,1163
	Methyl methacrylate	Vinylidene fluoride	Single T_g	Blend had 30–80 wt.% III	474
Ethylene, chlorinated	Natural rubber, epoxidized	Vinyl chloride	Single T_g	II was 50 mol% epoxidized	394
Ethylene, chlorosulfonated	Natural rubber, epoxidized	Nitrile rubber, carboxylated	Single T_g	I had 35% Cl and 1% S (Hypalon-40); II was 50 mol% epoxidized; III was Krynac-211	702
Ethylene glycol	Vinyl acetate	*p*-Vinyl phenol	Single T_g; FTIR	Three miscible binary pairs; there was an immiscibility loop in the phase diagram	491,1240
Hexafluoroacetone-*co*-vinylidene fluoride	Methyl methacrylate	Vinyl acetate	Single T_g	I had 9 mol% hexafluoro-acetone	1073
Methyl acrylate	Vinyl acetate	*p*-Vinylphenol	Single T_g	Miscible at all compositions	1240
Methyl acrylate-*co*-styrene	Vinyl acetate	*p*-Vinylphenol	Single T_g	I had 28 wt.% styrene	1240
Methyl methacrylate	Vinyl acetate	Vinylidene fluoride	Single T_g	–	956
Natural rubber, epoxidized	Nitrile rubber, carboxylated	Chloroprene	Single T_g	I was 50 mol% epoxidized; II was Krynac-211; I/II/III = 1/1/1	14
Neopentyl glycol adipate	Vinyl chloride	Vinylidene fluoride	Single T_g	III < 50 wt.%	490
Styrene-*co*-4-vinylpyridine	Vinyl acetate	*p*-Vinylphenol	Single T_g	I had 30 wt.% styrene	1240

TABLE 4. POLYMER PAIRS MISCIBLE IN THE AMORPHOUS STATE AT ROOM TEMPERATURE, MOLECULAR WEIGHT DEPENDENCE INVESTIGATED

Polymer I of	Polymer II of	Method	Comments	Refs.
Acrylonitrile-*co*-α-methylstyrene	Carbonate of bisphenol-A	Single T_g; transparency	I had 9–12 wt.% AN; miscible when II had $M_w = 3.8$ kg/mol; immiscible when II had $M_w = 9.9$ kg/mol	930
Acrylonitrile-*co*-styrene	Carbonate of bisphenol-A	Single T_g; transparency	I had 24.6 wt.% AN and II had $M_w =$ 3.8 kg/mol; miscible when I had $M_w =$ 3.137 kg/mol and immiscible with I had $M_w = 6.085$ kg/mol	932
3-Bromo-2,6-dimethyl-1,4-phenylene ether	Styrene	Single T_g; transparency	I had MW ≤40 kg/mol; II had MW ≤30 kg/mol	529
n-Butyl methacrylate	Styrene	Single T_g; transparency	I had $M_w = 320$ kg/mol; II had MW = 171 kg/mol; two T_g's when II had MW = 1100 kg/mol	193
Carbonate of bisphenol-A	Ester	Single T_g	II was made from 4,4′-(2-norbornyl-idene)di-phenol and a mixture of terephthalic acid and azelaic acid; miscible with I had $M_w = 28.1$ kg/mol; immiscible when I had $M_w = 73.2$ kg/mol	1232
2,6-Dimethyl-1,4-phenylene ether	Alkylstyrene	Transparency	I had $M_w = 5$–500 kg/mol and II was a ring-alkyl (with various carbon atoms) styrene. Raising MW of II eventually produced a transition from clear to hazy or cloudy films in each system except that containing poly-α-methylstyrene. With this resin, clear single-T_g films were obtained even with M_w of I = 500 kg/mol and M_w of II = 800 kg/mol	403
	p-Bromostyrene	Transparency	II had $M_n = 29.1$ kg/mol and $M_w = 32$ kg/mol; M_w limit for miscibility in 50/50 blend of I with II was 6.2 ± 2.4 kg/mol. When II had $M_n = 6.4$ kg/mol and $M_w = 7.04$ kg/mol, M_w limit for miscibility of I was 14 ± 4 kg/mol	403
	p-*tert*-Butylstyrene	Transparency	II had $M_n = 113$ kg/mol and $M_w = 289$ kg/mol; M_w limit for miscibility in 50/50 blend of I with II was 4.5 kg/mol ± 0.7 kg/mol	403

TABLE 4. *cont'd*

Polymer I of	Polymer II of	Method	Comments	Refs.
	4-Ethylstyrene	Transparency	II had $M_n = 139$ kg/mol and $M_w = 158$ kg/mol; M_w limit for miscibility in 50/50 blend of I with II was 22.4 kg/mol	403
	4-Methoxystyrene	Transparency	II had $M_n = 282$ kg/mol and $M_w = 457$ kg/mol; M_w limit for miscibility in 50/50 blend of I with II was 3.6 kg/mol	403
	4-Methylstyrene	Transparency	II had $M_n = 118$ kg/mol and $M_w = 265$ kg/mol; M_w limit for miscibility in 50/50 blend of I with II was 35.5 kg/mol	403
	4-*n*-Propylstyrene	Transparency	II had $M_n = 128$ kg/mol and $M_w = 267$ kg/mol; M_w limit for miscibility in 50/50 blend of I with II was 14 ± 4 kg/mol	403
	Vinylbenzylchloride	Transparency	II had $M_n = 16.8$ kg/mol and $M_w = 29.3$ kg/mol; M_w limit for miscibility in 50/50 blend of I with II was 14 ± 4 kg/mol	403
	4-Vinylbiphenyl	Transparency	II had $M_n = 79$ kg/mol and $M_w = 153$ kg/mol; M_w limit for miscibility in 50/50 blend of I with II was 7 ± 1.6 kg/mol	403
	Vinylnaphthalene	Transparency	II had $M_n = 13$ kg/mol and $M_w = 32.6$ kg/mol; M_w limit for miscibility in 50/50 blend of I with II was 10.2 kg/mol	403
	Vinyltoluene	Transparency	II had $M_n = 20.7$ kg/mol and $M_w = 40.4$ kg/mol; M_w limit for miscibility in 50/50 blend of I with II was 69 ± 25 kg/mol	403
Ethylene	Dimethylsiloxane	Cloud point curve	I was oligomeric polyethylene with $M_w = 0.254$ to 2.234 kg/mol and II was oligomeric polydimethylsiloxane with $M_w = 0.505$ to 4.5 kg/mol	584
Ethylene glycol	Propylene glycol	Miscibility stated	I and II both had MW < 1 kg/mol	65
	Vinyl acetate	Single T_g	I had $M_w = 20$ kg/mol miscible with II; I had $M_w = 100$ kg/mol miscible with II when blend had $\leq 50\%$ II	328
	Sulfone	Scattering turbidimetry	Blends with II >40 wt.% were homogeneous when I had MW = 3.5–4.5 kg/mol and II had MW = 35.6 kg/mol. Blends were heterogeneous at all compositions when I had MW = 200 kg/mol	796
Hydroxybutyrate	Lactide	Microscopy	Miscible when II had $M_n = 1.759$ kg/mol; immiscible when II had $M_n = 159.4$ kg/mol	923
cis-Isoprene	Styrene	Single dynamic mechanical loss peak	I was natural rubber; II had $M_w \leq 0.375$ kg/mol; two peaks when II had $M_w \geq 0.6$ kg/mol	140
	Vinyl cyclohexane	Single dynamic mechanical loss peak	I was natural rubber; II had $M_w \leq 0.375$ kg/mol; two peaks when II had $M_w \geq 0.65$ kg/mol	140
Methyl methacrylate	Carbonate of bisphenol-A	Single T_g; transparency	Miscible when M_w of I/II were 2.4 kg/mol/38 kg/mol, 10.55 kg/mol, 38 kg/mol, 60 kg/mol/9.9 kg/mol, 105 kg/mol;/9.9 kg/mol; immiscible when M_w of I/II were 20.3 kg/mol;/38 kg/mol, 33.5 kg/mol;/25.9 kg/mol, 33.5 kg/mol;/38 kg/mol and 60 kg/mol;/38 kg/mol	930
	Carbonate of hexafluorobisphenol-A-*co*-carbonate of tetramethylbisphenol-A	Single T_g; transparency	II had 60 wt.% HFPC and $M_w = 33$ kg/mol, and miscible when I had $M_w =$ 4–9.9 kg/mol; when II had $M_w =$ 103 kg/mol, it was miscible with I having $M_w = 4$ kg/mol and 11 kg/mol only	1194
	Styrene	Single T_g, transparency	Miscible when I had $M_w = 2.4$ kg/mol and II had $M_w = 2.95$ kg/mol; blends showed UCST when I and II had higher M_w (Ref. 929)	640,804, 929
	α-Styrene	Single T_g; transparency	Immiscible when I had $M_w = 6.7$ kg/mol and II had $M_w = 105.5$ kg/mol; miscible when I and II had lower M_w	929
	Sulfone	Single T_g; transparency	Miscible when I had $M_w = 1.21$ kg/mol or and 2.4 kg/mol and II had $M_w = 12$ kg/mol; immiscible when I had $M_w = 4.25$ kg/mol and II had $M_w = 34$ or 44 kg/mol	931

References page VI-461

TABLE 4. *cont'd*

Polymer I of	Polymer II of	Method	Comments	Refs.
Methyl methacrylate-*co*-styrene	Styrene	Single T_g; transparency	I had 26% styrene and II had MW = 0.6 kg/mol or I had 62.6% styrene and II had MW ≤ 2.1 kg/mol or I had 80% styrene and II had MW ≤ 4 kg/mol	557,804
α-Methylstyrene	Styrene	Single T_g; transparency; neutron scattering	Miscible when I had M_w = 55 kg/mol and II had M_w = 22 or 52 kg/mol; immiscible when II had M_w = 341 kg/mol (Ref.929)	38,42,63, 159,203, 691,710, 721,822, 865,929
	Styrene, deuterated	Single T_g	I had M_n = 25.8–78.3 kg/mol; II had M_n = 36.1–84.1 kg/mol	671
α-Methylstyrene-*co*-styrene	Styrene	Single T_g	I had M_n = 59–818 kg/mol; II had 3–79 mol% α-methylstyrene	159
Propylene	Ethylene-*co*-propylene	Single T_g	Miscible when I had M_w = 33 kg/mol and II had M_w = 44.5 kg/mol; immiscible when I and II had higher M_w	1101
Styrene	Carbonate of bisphenol-A	Single T_g; transparency	I had M_w = 0.58, 0.68, 0.95 or II had M_w = 3.8, 9, 25.9 or 38 kg/mol; miscibility depended on M_w and composition of blend	930
	Carbonate of dimethylbisphenol-A	Single T_g; transparency	II had M_w = 30 kg/mol; miscible when I had M_w = 0.58, 0.68 or 0.95 kg/mol; immiscible when I had M_w = 2.95 kg/mol	930
	Carbonate of tetramethylbisphenol	Single T_g; transparency	II had M_w = 31 kg/mol; miscible when I had M_w = 2.95 kg/mol; partially miscible when I had M_w = 9.2 or 17.5 kg/mol; immiscible when I had M_w = 341 kg/mol	930
	o-Chlorostyrene-*co*-*p*-chlorostyrene	Single T_g	I had M_n = 2.2–93 kg/mol; II had 7–100 mol% *o*-chlorostyrene	131
	Vinyl methyl ether	Single T_g	I had mol. wt. 0.8–233 kg/mol; II had mol. wt. 1.0–97.5 kg/mol	878,724
	2-Vinyl naphthalene	Single T_g	I had MW = 2.2 kg/mol; II had MW ≤ 70 kg/mol	731
p-Vinylphenol	Diethyl itaconate	Single T_g	II had M_w = 9.4 kg/mol and was miscible with I having M_w = 1.5–7 kg/mol, 9–11 kg/mol;, 22 or 30 kg/mol; II had M_w = 61 kg/mol and was miscible with I having M_w = 1.5–7 kg/mol and 9–11 kg/mol	1034

TABLE 5. POLYMER PAIRS THAT APPEAR TO HAVE HIGH TEMPERATURE MISCIBILITY, ALTHOUGH IMMISCIBLE AT OR BELOW ROOM TEMPERATURE (UCST BEHAVIOR)

Polymer I of	Polymer II of	Comments	References
Acrylonitrile-*co*-styrene	Sulfone of tetramethylbisphenol-A	I had 9 wt.% AN and II had M_w = 4.8 kg/mol; I had 11 wt.% AN and II had M_w = 12.4 kg/mol	931
Aramide	Imide	I was Aramid 341; II was Polyimide UR	1136
Butadiene	Butadiene	I had 98% *cis*-1,4; II had 71% vinyl-1,2 and 19% *trans*-1,4	736
	Butadiene, perdeuterated	Both I and II were *cis*-1,4	49
	Butadiene-*co*-styrene	I was *cis*-1,4; II had 23–30 wt.% styrene	362,650,737, 797,1121
	Styrene	II was hydrogenated or partly deuterated, I and II had MW = 2.0 kg/mol (Ref. 516); I had M_w = 0.96 kg/mol and II had M_w = 9.0 kg/mol (Ref. 808)	516,808
	Terpene resin, hydrogenated	I had 10–70.4% 1,2-content	1062
Butadiene-*co*-styrene	Styrene	II was hydrogenated or partly deuterated; II was 68.4 wt.% styrene and had MW of 10 kg/mol and II had MW of 100 kg/mol	516

TABLE 5. *cont'd*

Polymer I of	Polymer II of	Comments	References
Caprolactone	Ester	II was made from adipoyl chloride and 4,4′-bis(6-hydro-hexyloxy)biphenyl	821
Carbonate of bisphenol-A	Methacrylic acid-*co*-styrene	II had 4–23 wt.% methacrylic acid	10
	Liquid crystalline polymer of biphenyl-4,4′-ylene sebacate	Blend had 50–80 wt.% II	387
	Segmented copolyetherester	I had a hard tetramethylene terephthalate segment and a soft polytetramethylene-ether-glycol terephthalate segment	1015
Chlorostyrene-*co*-styrene	2,6-dimethyl-1,4-phenylene oxide	I had 32.9 mol% styrene	234,863
Cyclohexyl methacrylate	Cyclohexyl acrylate	–	765
2,2-Dimethyl-1,3-propylene sebacate	Haloalkyl methacrylate	II had a haloalkyl group of 2-bromoethyl, 2-chloroethyl, 3-chloropropyl or 2-iodoethyl (4 blend systems)	611,1137,1111
Dimethylsiloxane	Methyl ethyl siloxane	–	341
	Phenyl methyl siloxane	–	469
Epoxy	Acrylonitrile-*co*-butadiene, carboxyl terminated	I was Epon 828, $M_n = 0.38$ kg/mol; II had 17 wt.% acrylonitrile, $M_n = 3.5$ kg/mol	492
	2,6-Dimethyl-1,4-phenylene oxide	II was diglycidyl ether of bisphenol-A	1148
Ether ether sulfone	Ether ether ketone-*co*-ether ether sulfone	II had 50% ether ether sulfone	740
Etherimide	Ethylene terephthalate-*co*-ethylene naphthalate	The higher the ethylene naphthalate content in II, the lower the UCST	1072
Ethyl methacrylate	Ethyl acrylate	–	766
Ethylene	Propylene	II was atactic; no UCST when II was isotactic; from high temperature phase diagrams	452
Ethylene, chlorinated	Ethylene, chlorinated	Cl contents = 40-50 wt.%	816
Hemicellulose	Lignin	Blend had 10, 80 or 90 vol% of II	1188
Isophthalamide-6I (iminoiso-phthaloyl-iminohexamethylene)	Hexamethylene adipamide (nylon 6,6)	Interchange reaction slow	899
Isoprene	Vinylethylene	II was syndiotactic and had 92% vinyl-1,2-	363
Maleic anhydride-*co*-styrene	Sulfone of tetramethylbisphenol-A	I had 14 wt.% maleic anhydride; II had $M_w = 4.8$ kg/mol	931
Methyl methacrylate	Carbonate of dimethylbisphenol-A	I had $M_w = 1.21$ or 2.4 kg/mol; II had $M_w = 33$ kg/mol	930
	Carbonate of tetrachlorobisphenol-A	I had $M_w = 1.21$ kg/mol; II had $M_w = 41$ kg/mol	930
	Carbonate of tetramethylbisphenol-P	I had $M_w = 1.21$ or 2.4 kg/mol; II had $M_w = 31$ kg/mol	930
	Hydroxybutyrate	–	1189
	Styrene	I had $M_w = 2.03$–6.0 kg/mol; II had $M_w =$ 1.95–9.2 kg/mol	558,929,1146
	Sulfone of tetramethylbisphenol-A	I had $M_w = 1.21$ or 2.4 kg/mol; II had $M_w = 4.8$ or 12.4 kg/mol	931
	Sulfone of tetramethylhexafluoro-bisphenol-A	I had $M_w = 1.21$ kg/mol; II had $M_w = 40$ kg/mol	931
	Sulfone of tetramethylbisphenol-P	I had $M_w = 1.21$ kg/mol; II had $M_w = 40$ kg/mol	931
	Vinyl chloride	–	674
1,3-Phenylene adipamide	Hexamethylene adipamide (nylon 6,6)	I was made from *m*-phenylenediamine and adipic acid; interchange reaction slow	899
Styrene	Caprolactone	I had $M_n = 0.95$ kg/mol	629
	Carbonate of bisphenol chloral	I had $M_w = 0.58$ or 0.68 kg/mol; II had $M_w = 30$ kg/mol	930
	α-Methylstyrene	UCST increased with molecular weight	514
	o-Methylstyrene	–	24
	p-Methylstyrene	–	24,786
	m-Methylstyrene	–	24
	Styrene, brominated	II had 27 or 29 mol% brominated units	784
	Styrene, deuterated	–	48,879
	Sulfone of tetramethylbisphenol-A	I had $M_w = 1.21$ or 2.4 kg/mol; II had $M_w = 4.8$ or 12.4 kg/mol	931
	Sulfone of tetramethylbisphenol-P	I had $M_w = 1.21$ kg/mol; II had $M_w = 40$ kg/mol	931
	Sulfone of tetramethylhexafluorobisphenol-A	I had $M_w = 1.21$ kg/mol; II had $M_w = 40$ kg/mol	931
	Vinyl methyl ether	By extrapolation of solution data	168
Vinyl chloride	Acrylonitrile-*co*-methyl methacrylate-*co*-α-methylstyrene	II had 32.3 wt.% AN, 8.1 wt.% MMA and 59.6 wt.% α-MS; blend had 50–80 wt.% II	1078
Vinylidene fluoride	Methyl methacrylate	–	809
Vinylidene fluoride-*co*-tetrafluoroethylene	Vinylidene fluoride-*co*-hexafluoroacetone	I had 80 mol% vinylidene fluoride; II had 92 mol% vinylidene fluoride	951

TABLE 6. POLYMER PAIRS MISCIBLE AT ROOM TEMPERATURE THAT APPEAR TO HAVE A LOWER CRITICAL SOLUTION TEMPERATURE (LCST) ABOVE ROOM TEMPERATURE

Polymer I of	Polymer II of	Comments	Refs.
Acrylic acid, Li-neutralized	Ethylene oxide	0.1–0.4 mole fraction of I was neutralized	1115
Acrylic acid-*co*-styrene	Ethyl methacrylate	I had 8.84 wt.% acrylic acid	72
	Methyl methacrylate	I had 2.65–20.0 wt.% acrylic acid	384,856
	n-Propyl methacrylate	I had 2.65–8.84 wt.% acrylic acid	856
Acrylonitrile-*co*-butadiene-*co*-methyl acrylate	Ethylene-*alt*-maleic anhydride	I was Barex 210	1156
Acrylonitrile-*co*-α-methyl styrene	Acetonyl methacrylate	I had 30 wt.% acrylonitrile (AN)	266
	n-Butyl methacrylate	I had 12 wt.% AN	152
	n-Butyl methacrylate-*co*-methyl methacrylate	I had 30 wt.% AN; II had 70 wt.% methyl methacrylate	289
	Carbonate of tetramethylbisphenol-A	I had 4–16.5 wt.% AN	1010
	Ethyl methacrylate	I had 30 wt.% AN (Ref. 277); II had 10–28 wt.% AN (Ref. 152)	152,277
	Ethyl methacrylate-*co*-methyl methacrylate	I had 30 wt.% AN; II had 60 wt.% methyl methacrylate	289
	Methoxymethyl methacrylate	I had 30 wt.% AN	266
	Methyl methacrylate	I had 30 wt.% AN and II was atactic or isotactic (Ref. 277); I had 31.3, 33.1, 34.8 or 41.3 wt.% AN (Ref. 790); I had 10–37 wt.% AN (Ref. 152)	152,277,790, 1010
	Methyl methacrylate-*co*-2,2,6,6-tetramethyl-piperidinyl methacrylate	I had 30 wt.% AN; II had ≥76.2 wt.% methyl methacrylate)	272,274
	Methylthiomethyl methacrylate	I had 30 wt.% AN	268
	n-Propyl methacrylate	I had 17–20 wt.% AN	152
	Tetrahydrofurfuryl methacrylate	I had 30 wt.% AN	281
	Vinyl chloride	I had 11.9–30 wt.% AN	1010
Acrylonitrile-*co*-*p*-methylstyrene	Acetonyl methacrylate	I had 43.0–61.0 wt.% AN	121
	n-Butyl methacrylate	I had 13.6 wt.% AN	285
	Cyclohexyl methacrylate	I had 15.8–21.3 wt.% AN	120
	Ethyl methacrylate	I had 26.5–32.3 wt.% AN	285
	n-Propyl methacrylate	I had 21.3–26.5 wt.% AN	285
	Tetrahydrofurfuryl methacrylate	I had 32.3–46.5 wt.% AN	285
	Tetrahydropyranyl-2-methyl methacrylate	I had 23.8–26.5 wt.% AN	119
Acrylonitrile-*co*-styrene	Acetonyl methacrylate	I had 33–58 wt.% AN	121
	Acrylonitrile-*co*-methyl methacrylate	Some blends showed LCST	620
	Butyl methacrylate-*co*-methyl methacrylate	Some blends showed LCST	405
	Caprolactone	I had 24–28 wt.% AN	565,1145
	Copolycarbonate of bisphenol-A and tetramethylbisphenol-A	Some blends showed LCST, depending on compositions of I and II	431
	Cyclohexyl methacrylate	I had 13.4–19.8 wt.% AN	120
	2,6-Dimethyl-1,4-phenylene ether, benzoylated	I and 18 mol% AN; II had 35% benzoylated unit	776
	Ethyl methacrylate	I had 5.5–28 wt.% AN	229,489
	Maleic anhydride-*co*-styrene	Some blends showed LCST	436,462,555
	Methoxymethyl methacrylate	I had 30 wt.% AN	258
	Methyl methacrylate	I had 9.4, 9.8, 27.0, 28.2, 30.5 or 34.4 wt.% AN (Ref. 506); I had 29.4–39.3 wt.% AN (Ref. 164)	56,164, 460,506,566
	Methyl methacrylate-*co*-2,2,6,6-tetramethyl-piperidinyl methacrylate	I had 22 or 30 wt.% AN; II had 69, 74 or 85.5 wt.% methyl methacrylate	272,274
	Methyl methacrylate-*co*-*N*-phenylmaleimide	I had 24.6 wt.% AN; II had 23.5 wt.% *N*-phenylmaleimide	185
	Methylthiomethyl methacrylate	I had 34.5 wt.% AN	269
	Phenyl acrylate	I had 14.6, 29.9 or 34.1 wt.% AN	717
	n-Propyl methacrylate	I had 5.7–19.5 wt.% AN	229,1090
	Tetrahydrofurfuryl methacrylate	I had 34.5–46.6 wt.% AN	286
	Tetrahydropyranyl-2-methyl methacrylate	I had 2.2 or 22–30.5 wt.% AN	119
	Vinyl chloride	I had 11.5–26 wt.% AN	437
Aniline, *N*-octadecylated	Ethylene-*co*-vinyl acetate	I was 60.2% alkylated; II had 20 wt.% vinyl acetate	1246
Aramide	Caprolactam-*co*-laurolactam	I was Trogmid T; II had 43.8 mol% caprolactam	213
Arylsulfone	Imide	I was Radel A; II was XU 218	375
2-Bromoethyl methacrylate	Vinyl acetate	Blends cast from methyl ethyl ketone	610
Butadiene	Butadiene	I had 50% vinyl-1,2, 35% *cis*-1,4 and 15% *trans*-1,4; II had 55% *trans*-1,4, 35% *cis*-1,4 and 10% vinyl-1,2	736
	Isoprene	I had ≤59% 1,4 content and II was *cis*-1,4 isomer (Ref. 810); I was deuterated and II was protonated (Ref. 335)	335,810
Butyl acrylate	Ethylene, chlorinated	–	100
	Vinyl chloride	–	655,845,850,851

TABLE 6. *cont'd*

Polymer I of	Polymer II of	Comments	Refs.
Butyl methacrylate	*p*-(2-Hydroxy-hexafluoroisopropyl)styrene-*co*-styrene	II had 90.3–90.8 mol% styrene	646
N-butyl-3-hydroxymethyl-carbazoyl methacrylate	ω-Hydroxybutyl-3,5-dinitrobenzoyl methacrylate	–	298
p-tert-Butylstyrene	Cyclohexyl acrylate	–	765
	Cyclohexyl methacrylate	–	765
Caprolactone	Ethylene, chlorinated	II had 30 or 42.1 wt.% Cl	53,191
	Vinylidene fluoride	Blends rich in I showed LCST	386
Carbon monoxide-*co*-ethyl acrylate-*co*-ethylene	Vinyl chloride	I had 13.8/7.41/78.8 = carbon monoxide/ethyl acrylate/ethylene	692
Carbonate of bisphenol-A	Caprolactone	–	56,177,645
	Cyclohexyl methacrylate-*co*-methyl methacrylate	II had ≤ 3.3 wt.% cyclohexyl methacrylate (Ref. 574); II had 14.7–34.3 wt.% cyclohexyl methacrylate (Ref. 81)	81,574
	Methyl methacrylate	Blends prepared by precipitation of tetrahydrofuran solutions by *n*-heptane; or by solution casting from tetrahydrofuran at high temperature	109,481,486
	Methyl methacrylate-*co*-*p*-methylstyrene	II had ≥ 70 wt.% methyl methacrylate	357
	Methyl methacrylate-*co*-*N*-phenylmaleimide	II had ≥ 70 wt.% methyl methacrylate	357
	Methyl methacrylate-*co*-phenyl methacrylate	II had 16–63 wt.% phenyl methacrylate	81
	Methyl methacrylate-*co*-styrene	II had ≤ 14 wt.% styrene	577
Carbonate of hexafluorobisphenol-A	Alkyl methacrylate	II had an alkyl group of ethyl, *n*-propyl or isopropyl (3 blend systems)	427,430
Carbonate of tetramethylbisphenol-A	Acrylonitrile-*co*-styrene	II had 2 or 11.5% acrylonitrile	225
	Methyl methacrylate-*co*-styrene	II had 4.5, 32.5, 33.5 or 35 wt.% methyl methacrylate (Ref. 575); II had 4.5–33.5 wt.% methyl methacrylate (Ref. 429)	429,575,884
	Styrene	I had M_w = 341 kg/mol; II had M_w = 33 kg/mol	359,428,741,930
Carbonate of tetramethylbisphenol-P	Styrene	I had M_w = 9.2 kg/mol; II had M_w = 31 kg/mol	930
Caprolactone	Styrene-*co*-*p*-vinylphenol	II had 10 wt.% vinylphenol	905
	Vinyl methyl ether	–	1145
Cellulose acetate	4-Vinylpyridine	I was 10H/2 glucose	86
1-Chloroethyl methacrylate	Alkyl methacrylate	II had an alkyl group of ethyl, *n*-propyl, isopropyl or *n*-butyl (4 blend systems)	1152
2-Chloroethyl methacrylate	Ethyl methacrylate	–	612
Chloromethyl methacrylate	Alkyl methacrylate	II had an alkyl group of ethyl, isopropyl or *n*-propyl (3 blend systems)	273
o-Chlorostyrene	Styrene	–	15
o-Chlorostyrene-*co*-*p*-chlorostyrene	Styrene	I had 71–92 mol% *o*-chlorostyrene	803
2,2-Dichloroethyl methacrylate	Alkyl methacrylate	II had an alkyl group of *n*-propyl, isopropyl, *n*-butyl or isoamyl (4 blend systems)	1110
2,6-Dimethyl-1,4-phenylene ether	Acrylic acid-*co*-styrene	II had 6.3 or 8.5 wt.% acrylic acid	1022
	Acrylonitrile-*co*-styrene	II had 6.3 wt.% acrylonitrile	1022
	o-Chlorostyrene-*co*-*p*-chlorostyrene	–	16
	o-Chlorostyrene-*co*-*o*-fluorostyrene	II had about 14–40 mol% *o*-chlorostyrene	840,841
	p-Chlorostyrene-*co*-*o*-fluorostyrene	II had 66–74 mol% *p*-chlorostyrene	840,841
	o-Fluorostyrene-*co*-*p*-fluorostyrene	II had 10–38% *p*-fluorostyrene	835
	o-Fluorostyrene-*co*-*p*-bromostyrene	II had 68 or 73 mol% bromostyrene	834
	o-Fluorostyrene-*co*-styrene	II had 9–20 mol% styrene	839,842
	p-Fluorostyrene-*co*-styrene	II had about 22–54 mol% styrene	531,839,842
	Maleic anhydride-*co*-styrene	II had 4.6–9.9 wt.% MA (Ref. 1226); II had 7.3–12.5 wt.% MA (Ref. 1022)	1022,1226
	Methyl methacrylate-*co*-styrene	II had 12.5–20 wt.% methyl methacrylate	1022
2,6-dimethyl-1,4-phenylene ether, sulfonylated	*o*-Fluorostyrene	I had 4–17 mol% sulfonylated units	1220
	p-Fluorostyrene	I had 17–66 mol% sulfonylated units	1220
	Phenylvinyl *sec*-butyl ether-*alt*-*N*-phenylmaleimide	I had 87 mol% sulfonylated units	1219
	Phenylvinyl ethyl ether-*alt*-*N*-phenylmaleimide	I had 87 or 91 mol% sulfonylated units	1219
Dodecamethylene decamethylene dicarboxylate	Vinyl chloride	–	872
Dodecamethylene dodecamethylene dicarboxylate	Vinyl chloride	–	872
	Vinyl chloride-*co*-vinylidene chloride	II had 13.5 wt.% vinyl chloride	873

References page VI-461

TABLE 6. *cont'd*

Polymer I of	Polymer II of	Comments	Refs.
Epichlorohydrin	Alkyl acrylate	II had an alkyl group of ethyl or *n*-propyl (2 blend systems)	224
	Alkyl methacrylate	II had an alkyl group of methyl, ethyl, *n*-propyl, *n*-butyl or cyclohexyl (5 blend systems)	224
	Ethyl acrylate rubber	–	226
	Vinyl acetate	–	305
	N-vinylpyrrolidone	–	300
Ether sulfone	Imide	II was Matrimide 5218	510
Ethyl acrylate	Hexafluoroacetone-*co*-vinylidene fluoride	II had 8 mol% hexafluoroacetone	411,1059
	Vinylidene fluoride	–	56,844
2-Ethylhexyl methacrylate, modified	Hexyl methacrylate-*co*-styrene, modified	I had 3–5% acrylic acid; II had 30% styrene and 5–15% 3-(dimethylamino) 2,2-dimethylpropyl methacrylate	766
N-ethyl-3-hydroxymethylcarbazoyl methacrylate	ω-Hydroxyalkyl-3,5-dinitrobenzoyl methacrylate	II had an alkyl group of butyl, hexyl, pentyl or propyl (4 blend systems)	694
Ethyl methacrylate	*p*-(2-hydroxy-hexafluoroisopropyl)styrene-*co*-styrene	II had 90.3–98.8 mol% styrene	646
	Vinyl chloride-*co*-vinylidene chloride	II had 86.5 wt.% vinylidene fluoride	870
	Vinylidene fluoride	I was syndiotactic or atactic; LCST below T_m of II if I had high MW isotactic	56,695,802
Ethyloxazoline	Aramid	–	532
	Ether sulfone	–	599
Ethylene, chlorinated	Ethylene-*co*-vinyl acetate	I had 35.4–52.6 wt.% Cl; II had 40–45 wt.% vinyl acetate	849
	Methyl methacrylate	I had 50–52 wt.% Cl	99,848
Ethylene orthophthalate	Vinyl acetate	I had $M_n = 9.5$ kg/mol; no LCST when I had $M_n = 5.1$ kg/mol	829
Ethylene ether	Enaminonitrile	–	585
	Ether sulfone	–	317,534,743,853
	Ethylene-*co*-vinyl acetate	–	129
	Sulfone	M_n of I = 3.5–4.5 kg/mol; II was Udel P1700	796
Ethylene-*co*-vinyl acetate	Hexafluoroacetone-*co*-vinylidene fluoride	I had 70% vinyl acetate; II had 8.9 mol% hexafluoroacetone	336
	Vinyl chloride	I had 30 or 37 wt.% ethylene	631,678
2-Fluoroethyl methacrylate	Alkyl methacrylate	II had an alkyl group of methyl or ethyl (2 blend systems)	1153
3-Fluoropropyl methacrylate	Methyl methacrylate	–	1155
Hexadecamethylene dodecamethylene dicarboxylate	Vinyl chloride	–	872
n-Hexyl methacrylate	Styrene-*co*-*p*-vinylphenol	II had 7 or 9 wt.% vinylphenol	922
Hydroxyether of bisphenol-A (phenoxy)	Alkyl methacrylate	II had an alkyl group of methyl, tetrahydrofurfuryl or tetrahydropyranyl-2-methyl (3 blend systems)	111,118,253
	Ether sulfone	–	714,764
	Ethylene oxide-*co*-propylene oxide	II had 22, 50 or 66 mol% ethylene oxide	1025
	Vinyl methyl ether	–	818
Hydroxyether of phenolphthalein	Butylene terephthalate	–	310
	Ether sulfone	–	306
	Ethylene glycol	–	309
β-Hydroxyethyl-3,5-dinitrobenzoyl methacrylate	*N*-alkyl-3-hydroxymethylcarbazoyl methacrylate	II had an alkyl group of butyl, decyl, dodecyl, ethyl, hexadecyl, hexyl, octyl or tetradecyl	693
2-(Hydroxyhexafluoroisopropyl) styrene-*co*-styrene	Methyl methacrylate	I had 90.3–96.1 mol% styrene	646
	Vinyl methyl ether	I had 90.3–99.9 mol% styrene	646
Hydroxypropyl Glutamine	Styrene-*co*-*p*-(hexafluoro-2-hydroxy-2-propyl)-α-methylstyrene	II had 98.5 mol% styrene; blend had < 50 vol% I	971
2-Iodoethyl methacrylate	Tetrahydrofurfuryl methacrylate	–	1107
Isoprene	*cis*-Butadiene-*co*-1,2-vinylbutadiene	II had $\leq$ 24.3% vinylbutadiene	420
Maleic anhydride-*co*-styrene	Ethyl methacrylate	I had 0–33 wt.% maleic anhydride	73
	Methyl methacrylate	I had 8, 10, 13 or 33 wt.% maleic anhydride	73
	n-Propyl methacrylate	I had 0–18.1 wt.% maleic anhydride	73
Methacrylonitrile-*co*-*p*-methylstyrene	*n*-Butyl methacrylate	I had 15–25 wt.% MAN	944
	Ethyl methacrylate	I had 40, 46 or 53 wt.% MAN	944
	Methyl methacrylate	I had 34, 53, 56 or 68 wt.% MAN	944
	Isopropyl methacrylate	I had 22–31 wt.% MAN and I had $M_n = 161$ kg/mol; II had 17–31 wt.% MAN and I had $M_n = 41.6$ kg/mol	944
	n-Propyl methacrylate	I had 37 or 40 wt.% MAN	944
Methacrylonitrile-*co*-styrene	Ethyl methacrylate	I had 5.6, 35.4 or 40.1 wt.% MAN	943

TABLE 6. *cont'd*

Polymer I of	Polymer II of	Comments	Refs.
	Methyl methacrylate	I had 46.6–62.8 wt.% MAN	1018
	n-Propyl methacrylate	I had 2–32 wt.% MAN	943
Methyl acrylate	Vinylidene fluoride	–	56,844
Methyl methacrylate	Acrylonitrile-*co*-methyl methacrylate-*co*-styrene	II had 40.0/39.1/20.9 or 61.1/19.6/19.3 of S/MMA/AN	620
	Carbonate of bisphenol chloral	–	110,930
	Copolycarbonate of bisphenol-A and hexafluorobisphenol-A	II had 5.3–14 wt.% hexafluorobisphenol-A	430
	Epichlorohydrin-*co*-ethylene glycol	II had 50 mol% ethylene glycol	224
	Ethylene, chlorinated	II had 56–68 wt.% Cl; I was atactic, isotactic or syndiotactic	1204
	Ethylene glycol	–	224
	Hexafluoroacetone-*co*-vinylidene fluoride	–	443
	N-maleimide-*co*-styrene	II had 8, 14 or 21 wt.% *N*-maleimide	1213
	Styrene-*co*-*p*-vinylphenol	I was syndiotactic; II had 5 mol% vinylphenol	1055
	Sulfone of hexafluorobisphenol-A	I had $M_w = 2.4$ kg/mol;, 1.21 or 4.25 kg/mol; II had $M_w = 27$ kg/mol or 56 kg/mol	931
	Tetrafluoroethylene-*co*-vinylidene fluoride	II had 80 mol% vinylidene fluoride	324
	Vinyl acetate	Blends cast from chloroform or cyclohexanone	302,777,778,1092
	Vinyl chloride	–	368,506,653,742
	Vinyl chloride, chlorinated	II had 63, 65 or 68 wt.% Cl	506,833
	Vinyl chloride-*co*-vinylidene chloride	I was atactic or isotactic; II had 86.5 wt.% vinylidene chloride	506,870
	Vinylidene fluoride	LCST above decomposition temperature of I	55
Methyl methacrylate, imidized	Acrylonitrile-*co*-styrene	I had 53–91 wt.% imidized unit; II had 5.7–33 wt.% acrylonitrile; some blends showed LCST	230
α-Methylstyrene	Carbonate of tetramethylbisphenol-A	I had $M_w = 3.5$ or 6.7 kg/mol; II had $M_w = 33$ kg/mol	930
	Carbonate of tetramethylbisphenol-P	I had $M_w = 3.5$ or 6.7 kg/mol; II had $M_w = 31$ kg/mol	930
	Ethyl methacrylate	–	765
	Methyl methacrylate	–	167,765
	n-Propyl methacrylate	–	765
	Styrene	–	710,722,865,929
	Tetrahydropyranyl-2-methyl methacrylate	–	116
α-Methylstyrene-*ran*-4-(2-hydroxyethyl)-α-methylstyrene	Alkyl acrylate	II had an alkyl group of methyl, ethyl or *tert*-butyl (3 blend systems)	968
	Alkyl methacrylate	II had an alkyl group of methyl, ethyl or *tert*-butyl (3 blend systems)	968
	Dialkyl itaconate	II had an alkyl group of methyl, ethyl, *n*-propyl, *n*-butyl or *tert*-butyl (5 blend systems)	968
	Vinyl acetate	–	969
	Vinyl pyrrolidone	–	969
	4-Vinylpyridine	–	969
α-Methylstyrene-*stat*-[4-(1,1,1-trifluoro-2-hydroxyethyl)-α-methylstyrene	Alkyl acrylate	II had an alkyl group of methyl, ethyl or *t*-butyl (3 blend systems)	968
	Alkyl methacrylate	II had an alkyl group of methyl, ethyl or *t*-butyl (3 blend systems)	968
	Dialkyl itaconate	II had an alkyl group of methyl, ethyl, *n*-propyl, *n*-butyl or *t*-butyl (4 systems)	968
	Vinyl acetate	–	969
	Vinyl pyrrolidone	–	969
	4-Vinylpyridine	–	969
Neopentyl glycol adipate (2,2-dimethyl-1,3-propylene adipate)	Hydroxyether of bisphenol-A (phenoxy)	–	332
Neopentyl glycol succinate (2,2-dimethyl-1,3-propylene succinate)	Hydroxyether of bisphenol-A (phenoxy)	–	332
	Vinyl chloride-*co*-vinylidene chloride	II was Saran, 86.5 wt.% vinylidene chloride; LCST above T_m when ≤ 50 wt.% I	868
Oxymethylene	Novolac	–	858
Phenol-formaldehyde	Methyl methacrylate-*co*-styrene	II had 30.4–83.5% MMA	433
p-Phenylene benzobisoxazole	Nylon	II was Zytel 330 (Du Pont) or nylon 6,6 (2 blend systems)	945
2,2′-(*m*-Phenylene)-5,5′-bibenzimidazole	Imide	II was Ultem 1000 or XU218 (2 blend systems)	114

TABLE 6. *cont'd*

Polymer I of	Polymer II of	Comments	Refs.
n-Propyl methacrylate	Vinyl chloride-*co*-vinylidene chloride	II had 86.5 wt.% vinylidene chloride	870
Styrene	Copolycarbonate of bisphenol-A and tetramethylbisphenol-A	II had ≥ 85 wt.% tetramethylbisphenol-A	431
	o-Fluorostyrene-*co*-*p*-fluorostyrene	I had $M_n = 7$ kg/mol; II had 10 or 33 mol% *p*-fluorostyrene	1144
Styrene, sulfonated and Zn-neutralized	Caprolactam (nylon 6)	I had 6.5, 8.1 or 9.0 mol% sulfonated units	1083
Styrene, sulfonated and neutralized	Caprolactam (nylon 6)	I was neutralized by Li, Mg or Zn	1223
Vinyl acetate	Hexafluoroacetone-*co*-vinylidene fluoride	–	1073
	Maleic anhydride-*alt*-styrene, hydrolyzed	II was 1.8–43% hydrolyzed; LCST increased with increasing degree of hydrolysis	67
Vinyl acetate-*co*-vinyl chloride	*n*-Butyl methacrylate	I had 5.9–15.1 vol% vinyl acetate	497
	Hexyl acrylate-*co*-methyl acrylate	I had 5–23.7 vol% vinyl acetate; II had 15–88 vol% hexyl acrylate; some blends showed LCST	379
	Methyl methacrylate	I had 5.9–15.1 vol% vinyl acetate	497
Vinyl butyral	Vinylpyridine	II was 2- or 4-vinylpyridine (2 blend systems)	1003
Vinyl chloride	Acrylonitrile-*co*-*n*-butyl acrylate	II had 53, 67 or 84 mol% butyl acrylate	655
	Alkyl acrylate	II had an alkyl group of *n*-propyl or *n*-amyl (2 blend systems)	851
	Alkyl methacrylate	II had an alkyl group of *n*-butyl or *n*-amyl (2 blend systems)	649,653
	Butyl acrylate-*co*-ethyl acrylate	II had 22.9, 43.5 or 52.8% butyl acrylate	851
	Butyl acrylate-*co*-hexyl acrylate	II had 47.8% butyl acrylate	851
	Butyl acrylate-*co*-methyl acrylate	II had 44.6% butyl acrylate	851
	Butyl acrylate-*co*-methyl methacrylate	II had 75% butyl acrylate	654
	Butyl methacrylate-*co*-methyl methacrylate	II had 30 or 70% methyl methacrylate	653
	Ethyl acrylate-*co*-hexyl acrylate	II had 41.7 or 43.2% ethyl acrylate	851
	Methyl acrylate-*co*-hexyl acrylate	II had 9.7% methyl acrylate	851
	Pentyl acrylate-*co*-propyl acrylate	II had 48.1% propyl acrylate	851
Vinyl methyl ether	Acrylonitrile-*co*-styrene	II had ≤ 10–11% acrylonitrile	575
	Alkyl acrylate	II had an alkyl group of ethyl or *n*-butyl (2 blend systems)	941
	2-Chlorostyrene	–	1203
	Hydrogeneous styrene-*b*-deuterated styrene	–	1019
	Maleic anhydride-*co*-styrene	II had < 15% maleic anhydride	575
	α-Methylstyrene	–	318
	α-Methylstyrene-*co*-4-(2-hydroxyethyl)-α-methylstyrene	II had 6–89 mol% α-methylstyrene	170
	α-Methylstyrene-*co*-4-(1,1,1-trifluoro-2-hydroxyethyl)-α-methylstyrene	II had 0–93 mol% α-methylstyrene	170
	α-Methylstyrene-*co*-styrene	II had 77.5 or 88 wt.% styrene	318
	m-Methylstyrene-*co*-styrene	II had 76.5 or 87.5 wt.% styrene	1028
	o-Methylstyrene-*co*-styrene	II had 76.2 or 86.8 wt.% styrene	1028
	p-Methylstyrene-*co*-styrene	II had 61–95 wt.% styrene	318,1016,1028
	Methyl methacrylate-*co*-styrene	II had < 60 mol% methyl methacrylate	108
	Nitrostyrene-*co*-styrene	II had ≤ 25.6 mol% Nitrostyrene	165,192
	Styrene-*co*-1-vinyl naphthalene	II had 17.4 wt.% styrene	318
	Styrene-*co*-2-vinyl naphthalene	II had 19.2 wt.% styrene	318
Vinyl methyl ketone	Styrene-*co*-4-vinylstilbene	Cloud point was sensitive to the *cis*- fraction of 4-stilbenzyl groups	365
p-Vinylphenol	4-Acetoxystyrene	–	340
2-Vinylpyridine	Aramide	II made from hexamethylenediamine and a mixture of isomers of phthalic acid	767
	2-Hydroxyethyl methacrylate	–	937
4-Vinylpyridine	Vinyl acetate-*co*-vinyl alcohol	II had 32–55 mol% vinyl alcohol	1046
Vinylidene fluoride	Methoxymethyl methacrylate	–	267

TABLE 7. POLYMER PAIRS THAT APPEAR TO HAVE BOTH A LOWER CRITICAL SOLUTION TEMPERATURE AND A UPPER CRITICAL SOLUTION TEMPERATURE

Polymer I of	Polymer II of	Comments	Refs.
Acrylonitrile-*co*-styrene	Acrylonitrile-*co*-butadiene	I had 25 wt.% acrylonitrile; II had 40 wt.% acrylonitrile	636
Butadiene	Butadiene-*co*-styrene	II had 45 wt.% styrene	797
Caprolactone	Acrylonitrile-*co*-styrene	II had 12.4–26.4 wt.% acrylonitrile	1193

Table 7. *cont'd*

Polymer I of	Polymer II of	Comments	Refs.
Carbonate of bisphenol-A	Methyl methacrylate	Blends showed a LCST-UCST loop	72,479,1085
Dimethylsiloxane	Methylphenylsiloxane	–	467
2-Hydroxyethyl Acrylate-*co*-liquid crystalline acrylate	2-Hydroxyethyl acrylate-*co*-liquid crystalline acrylate	Both I and II had 6% 2-hydroxyethyl acrylate; the liquid crystalline polyacrylates had different spacer groups	1252
o-Methylated phenol formaldehyde	Methyl methacrylate	I had 20 or 50% of OH group methylated	432
	Methyl methacrylate-*co*-styrene	I had 20 or 50% of OH group methylated; II had 50 or 60% methyl methacrylate	432
Styrene	2,6-Dimethyl-1,4-phenylene ether, carboxylated	II had 8.0–10.3 mol% carboxyl group	148

TABLE 8. POLYMER PAIRS THAT *CO*-CRYSTALLIZE

Polymer I of	Polymer II of	Method	Comments	Refs.
Butylene terephthalate	Butylene glycol-*b*-butylene terephthalate	T_g and T_m by DSC, dielectric loss measurements	Two T_g's when I was Valox 310 (General Electric) having $M_n = 20$ kg/mol and II contained 44–67 wt.% butylene terephthalate; single T_g and single T_m when II contained 85 wt.% butylene terephthalate; single T_m indicated that only one type of crystal was present	554
	Butylene glycol-*b*-butylene terephthalate	T_g and T_m by DSC, dielectric loss measurements, microscopy	Single T_g and single T_m when I was Valox 310 (General Electric) with $M_n = 33$ kg/mol, II contained 84 wt.% butylene terephthalate and I/II = 1/3 to 3/1; thermal analysis and morphological evidence pointed to extensive *co*-crystallization in this mixture; two T_g's when II contained 50 wt.% butylene terephthalate	703
	Ester–ether segmented polymer	Dielectric loss peak and T_m by DSC	I was Valox 310 (General Electric) with $M_n = 20$ kg/mol; II was comprised of a poly(butylene oxide) soft segment and a hard segment 4GT-butylene terephthalate, and had total MW = 25 to 30 kg/mol; single beta dielectric loss peak and single T_m were found when II was 44 or 67 wt.% 4GT; single T_m between the T_m's of the pure components indicated *co*-crystallization; two dielectric loss peaks and two T_m when II was 84 wt.% 4GT	704
Ether ether ketone	Ether ether ether ketone	T_g and T_m by DSC	Single T_g and single T_m when I contained 33% ketone linkages and had melt flow = 3.0 dg/min at 400°C and II had melt flow = 10 dg/min; I/II = 1/1	333
	Ether ether ketone ketone	T_g and T_m by DSC	Single T_g and single T_m when I contained 33% ketone linkages and had melt flow = 3.0 dg/min at 400°C and II contained 50% ketone linkages and had melt flow = 4.0 dg/min; I/II = 1/1	333
	Ether ketone	T_g and T_m by DSC	Single T_g and single T_m when I contained 33% ketone linkages and had melt flow = 3.0 dg/min and II contained 50% ketone linkages and had melt flow = 1.5 dg/min; I/II = 1/1	333
	Ether ketone	T_g and T_m by DSC; WAXD	Single composition-dependent melting endotherms obtained upon quenching when I had intrinsic viscosity = 1.124 dl/g in sulfuric acid at 30°C and II had intrinsic viscosity = 1.107 dl/g in sulfuric acid at 30°C, but it did not happen when other thermal histories were imposed	739
	Ether-*co*-ketone	T_g and T_m by DSC	Single T_g and single T_m when I contained 33% ketone linkages and had melt flow = 3.0	333

TABLE 8. *cont'd*

Polymer I of	Polymer II of	Method	Comments	Refs.
			dg/min and II contained 57% ketone linkages and had melt flow = 1.5 dg/min; I/II = 1/1	
	Ether ketone (polymer II), etherimide (polymer III)	T_g and T_m by DSC	I had reduced viscosity = 1.05 dl/g in 1 wt.% conc. sulfuric acid at 23°C; II had reduced viscosity = 1.9 dl/g in the same condition as for I; III was Ultem 1000 from GE with reduced viscosity = 0.5 dl/g in 0.2 wt.% chloroform at 25°C; single T_g and single T_m for I/II/III = 25/25/50	334
Ethylene	Butadiene, hydrogenated	DSC, SALS and SEM	I was narrow MW fraction with $M_w = 113$ kg/mol and $M_n = 105$ kg/mol; II contained 2.2–5.5 mol% ethyl branches and had $M_w = 103–420$ kg/mol and $M_n = 83–156$ kg/mol; stated that I and II *co*-crystallized upon rapid crystallization from the melt when II contained up to 2 mol% of ethyl branches	13
	Ethylene	DSC and SALS	I was polyethylene and II was UHMWPE with MW = 5,000 kg/mol; I was LLDPE (GRSN-7047 from Union Carbide with $M_w = 134$ kg/mol and $M_w/M_n = 4$), or I was HDPE (Chemplex 6186 with $M_w =$ 134.8 kg/mol and $M_w/M_n = 7.4$); only a single composition dependent T_m was observed; SALS showed the *co*-crystallization took place; but when I was LDPE ($M_w =$ 114 kg/mol and $M_w/M_n = 5.2$), separate crystals were formed	483
		DSC, SAXS and X-ray diffraction	I was linear LLDPE and II was HDPE; co-crystallization was evidenced by a single T_m by DSC; stated that X-ray diffraction peak width, SAXS and Raman spectra were all consistent with a single crystallizing species; but for HDPE/LDPE and LLDPE/LDPE, separate crystals were seen with two T_m's being found by DSC	783
			I was HDPE with $M_w = 100$ kg/mol and $M_n = 11$ kg/mol and II was LLDPE with $M_w = 350$ kg/mol and $M_n = 16$ kg/mol; after the blend with I/II = 25/75 by weight was crosslinked either by irradiation or by peroxides in the liquid state above a critical degree of cross-linkage, the DSC curve of the blend showed only one single melting point on heating and only one single crystallization peak on cooling; Refs. 45, 348, 478, 579 and 676 also discussed the miscibility of PE/PE blends	360
	Ethylene, deuterated	T_m by DSC	Single T_m varying smoothly with composition and no gross segregation occurred	217
Ethylene	Ethylene-*co*-vinyl acetate	DSC, SALS and SEM	I was narrow MW fraction with $M_w = 113$ kg/mol and $M_n = 105$ kg/mol; II contained 1.12–6.6 mol% of acetate branches and had $M_w = 60.3–105$ kg/mol and $M_n =$ 23.5–43.6 kg/mol; stated that I and II co-crystallized upon rapid crystallization from the melt contained up to 2 mol% of acetate branches	13
Ethylene-*co*-vinyl acetate	Ethylene-*co*-vinyl acetate	DSC, SALS and SEM	I and II had $M_w = 60.3–105$ kg/mol, $M_n =$ 23.5–43.6 kg/mol, and they were different in the content of acetate branches; stated that these copolymers containing about 1–2 mol% of acetate branches were found to co-crystallize with one another	13

TABLE 8. *cont'd*

Polymer I of	Polymer II of	Method	Comments	Refs.
Glutamate	Glutamate	Dynamic mechanical measurements, X-ray diffraction	I or II was poly(L-glutamate) or poly(D-glutamate) having *m* number of methylene group in the ester group of a general formula as $-CH_2CH_2COO-(CH_2)_m-C_6H_5-$, *m* might be 1, 2 or 3 so the component polymer would be represented as L*m* or D*m*; the MW of both components were 135 to 380 kg/mol and $M_w/M_n = 1.1$ to 1.2; stated that binary blends of L2, D2, L3 and D3 were miscible and formed isomorphous mixed crystals at all compositions, whereas other pairs, with the exception of L1/D1, were immiscible	717
Isopropyl vinyl ether, isotactic	*sec*-Butyl vinyl ether, isotactic	Unit cell dimension from X-ray diffraction	Co-crystallization at all compositions	605
4-Methyl-1-hexene, isotactic	4-Methyl-1-pentene, isotactic	Unit cell dimensions from X-ray diffraction	Co-crystallization only below 25 wt.% I and above 75 wt.% I	605
Tetrafluoroethylene	Tetrafluoroethylene-*co*-perfluoroalkyl vinyl ether	Dynamic mechanical measurements	II had 98–99 mol% tetrafluoroethylene; single α-transition from DMA	1173
Trifluoroethylene-*co*-vinylidene fluoride	Trifluoroethylene-*co*-vinylidene fluoride	DSC, X-ray and phase-contrast microscopy	No phase separation by phase-contrast microscopy, a sharp single X-ray peak, intermediate in spacing between those of the individual copolymers, and clearly different from their superposition, and only one ferroelectric transition and only one melting point by DSC, indicated co-crystallization within the same lattice when I was 52/48 mol% vinylidene fluoride (VDF)/trifluoroethylene (TFE), II was 65/35 mol% VDF/TFE, or I was 65/35 mol% VDF/TFE, and II was 73/27 mol% VDF/TFE; but two X-ray peaks and two ferroelectric transitions and two melting points when I was 52/48 and II was 73/27 mol% VDF/TFE	800
Vinyl alcohol	Vinyl alcohol	DSC	I and II had a diad syndiotacticity of 54 and 58 mol%, respectively	1197
Vinylidene fluoride-*co*-tetrafluoroethylene	Vinylidene fluoride		I had 9.1, 14.3 or 17.6 mol% tetrafluoroethylene	980
	Hexafluoroacetone-*co*-vinylidene fluoride	DSC	I had 80 mol% vinylidene fluoride; II had 92 mol% vinylidene fluoride; single melting peak	951

* The submitted manuscript has been authored by a contractor of the US Government under the contract No. DE-AC05-96OR22464. Accordingly, the US Government retains a non-exclusive, royalty-free license to publish, or reproduce the published form of this contribution, or allow others to do so, for US Government purposes.
** The work on the data bank mentioned in this chapter involved (in prior years) in particular Dr. U. Gaur, Dr. A. Mehta, Dr. S. F. Lau, and Dr. M. Varma-Nair. Financial support from the National Science Foundation, presently under Grant # DMR-9703692 (Polymers Program) was essential for the completion of the work. The present work is also supported by the Division of Materials Sciences, Office of Basic Energy Sciences, US Department of Energy at Oak Ridge National Laboratory, managed by Lockheed Martin Energy Research Corp. for the US Department of Energy, under contract number DE-AC05-96OR22464.
† General Note: The letters in parenthesis (after polymer names) correspond to the author's file number in Ref. 40, and are not necessarily the accepted abbreviation.

A. INTRODUCTION

The molar heat capacity at constant pressure, C_p, is defined as the amount of heat, Q, needed to raise the temperature, T, of one mole of substance at constant (atmospheric) pressure by one kelvin in the absence of latent heat effects, such as heats of fusion, crystallization,

reaction, etc. In differential form, one writes: $C_p \equiv dQ/dT = (\partial H/\partial T)_{p,n}$, [= heat capacity at constant pressure p, and number of moles, n (for polymers usually expressed per mole of repeating unit, *i.e.* for poly(propylene) per 0.04208 kg); H = enthalpy = $U + pV$ (U = total energy, V = molar volume)]. Frequently, one makes use of the specific heat capacity, c_p, which refers commonly to the heat capacity of one gram of material ($c_p \equiv C_p/M$, where M represents the molar mass of the repeating unit in Da).

The heat capacity is not only of theoretical interest, but has also considerable importance for practical applications, *e.g.*, for calculation of enthalpy differences between two temperatures or as the basis for interpretation of differential scanning calorimetry (DSC) curves. Furthermore, C_p is a basic quantity of thermodynamics. All integral functions can be derived from the data on C_p: the enthalpy, $H = \int C_p\,dT$, equal to the total heat content when integrated from 0 K to the temperature of interest and adding all intervening heats of transition, ΔH, at their equilibrium transition temperatures (energy and enthalpy are conserved as expressed by the first law of thermodynamics); the entropy, $S = \int (C_p/T)\,dT$, a measure of the degree of disorder of the sample, also to be integrated from 0 K to the temperature of interest and to be corrected by the intervening entropies of transition, ΔS (S = 0 J/K/mol for equilibrium crystals at 0 K and positive for all other temperatures and states–third law of thermodynamics; and the free enthalpy, $G = H - TS$, a measure of the stability of the sample (the state with the lowest free enthalpy is most stable – second law of thermodynamics). Figure 1 displays these integral functions for the example of polyethylene (PE, see Table 4) (34).

A representative experimental heat capacity measured by differential scanning calorimetry (DSC) is given in Fig. 2 for semicrystalline poly(oxyethyleneoxyterephthaloyl) (PET, see Table 37) (35). It can be seen that the heat capacity, C_p, given in J/K/mol, is not a single-valued function of temperature. It depends on the state of the polymer [crystalline, amorphous (solid or liquid), or semicrystalline]. The common semicrystalline samples, characterized by their weight fraction (or percentage) crystallinity w_c, are not in equilibrium, and their heat capacity depends on the thermal history since different cooling or annealing conditions may lead to different values of w_c. In addition, particularly in the melting region, the method of measurement, such as DSC or temperature-modulated DSC (TMDSC), may also yield different experimental answers (35). The TMDSC (heavy curve) is a measure of the limited reversibility of the melting of polymers, while the DSC curve is a measure of the breadth of the melting which arises from crystallite size-distributions and reorganization during melting (36).

In case of amorphous polymers (or the amorphous portion of a semicrystalline polymer) the heat capacity changes at the glass transition temperature, T_g, by ΔC_p, proportional to the weight fraction of amorphous material present, as shown in Fig. 3. In addition, the value of ΔC_p is often proportional to the number of flexible parts (beads) into which the repeating unit can be divided [$\approx$ 11 J/K (mol of beads)$^{-1}$ (34)]. The detailed apparent heat-capacity response of the sample in the glass-transition region is dependent on the thermal history of the substance under investigation and also on the heating rate of measurement. A maximum of heat capacity may be caused by enthalpy relaxation and may easily be confused with a melting process, as illustrated in Fig. 3, for atactic poly(styrene) (PS, see Table 20.). A number of other non-equilibrium processes that change the appearance of the heat capacity are (34): minima (exotherms) caused by stress relaxation that may be confused with a crystallization process, crystal perfection, annealing or fusion that add to or subtract from the heat capacity. Positive (endothermic) effects are usually indicative of disordering, negative (exothermic) effects are usually indicative of ordering (36).

Plotting ΔC_p versus ΔH allows extrapolation of data of semicrystalline samples to the completely amorphous and crystalline states, as shown in Fig. 4 (37). Negative deviations from the straight line exist for many stiffer polymers and indicate the presence of a rigid–amorphous fraction, *i.e.* a third phase in a semicrystalline sample that does not become mobile at the glass transition, but is not crystalline (three-phase model with the third phase most likely placed at the surfaces of the crystals where molecules continue into the amorphous phase). The effect of a rigid–amorphous phase on the heat capacity of poly(oxymethylene) is shown in Fig. 5 (38).

The heat capacity tables of this chapter contain mean values of the best data available in the literature. To make the tables universal, effects of broad glass transitions, thermal history, rigid–amorphous fractions, and effects of fusion, annealing, or crystallization were eliminated by appropriate extrapolation. Data for the "solid" refer to crystals as well as glasses. Only in the temperature range from 0 to perhaps 70 K are the heat capacities of glasses slightly higher than that for crystals. For semicrystalline samples between glass transition and melting, the crystallinity must be known. The heat capacity is then the sum of the heat capacities of the crystalline weight fraction and the melt weight fraction, as shown in Fig. 6. Fusion, annealing and crystallization, as well as glass transition broadening, must be added from additional experimental information, as illustrated above.

The tables given in this chapter are based on the ATHAS Data Bank of experimental heat capacities and its update for 1990 [U. Gaur, H. C. Shu, A. Mehta, S. F. Lau, B. B. Wunderlich, M. Varma-Nair, and B. Wunderlich, J. Phys. Chem. Ref. Data, **10**, 89, 119, 1001, 1051, (1981), **11**, 313, 1065, (1982), **12**, 29, 65, 91 (1983), and **20**, 349, (1991)]. The term "NA" in the value-column indicates that no recommendation of experimental data can be made at present; "NA" in the index-column is a reminder that the data point is gained by extrapolation of the experimental data due to transition effect.

The experimental data bank, as presented in this chapter, has been interpreted in terms of the molecular motion of the

polymers (39). The results of this extended data bank can be accessed over the World Wide Web (40). It contains data tables for over 200 polymer and polymer-related materials, including all poly(amino acids) and some proteins. In addition to the experimental data as shown in Tables 1–50, the ATHAS Data Bank contains a link of the solid heat capacity to approximate vibrational spectra as illustrated in Fig. 7 for poly(ethylene). Also, empirical addition schemes for the heat capacity of liquid and solid polymers have been developed, based on the molecular structure (41). An example is given in Fig. 8, for a series of aliphatic nylons (see also Tables 38–40).

B. EXPERIMENTAL CURVES

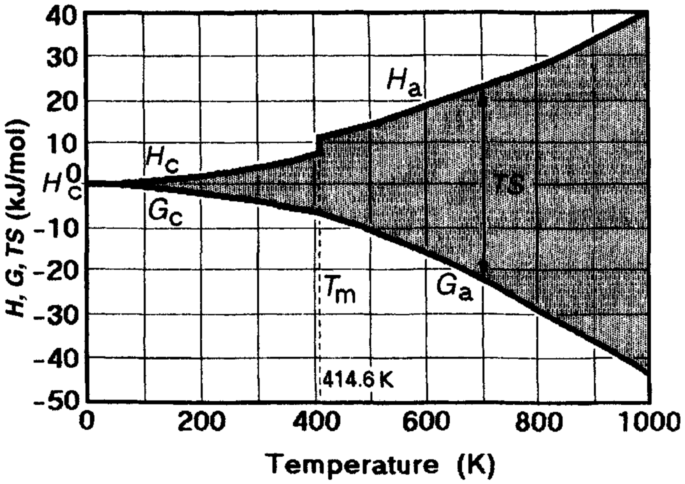

Figure 1. The integral thermodynamic functions H, G, and $TS = H - G$ for PE. The subscripts "a" refer to the amorphous, "c" to the crystalline samples; the equilibrium melting occurs at T_m; H_c^0 is set arbitrarily to zero, it can also be adjusted to the heat of formation $\Delta H_f(T)$ by adding the integral of C_p from 298.15 to 0 K to ΔH_f (298.15) (Ref. 34).

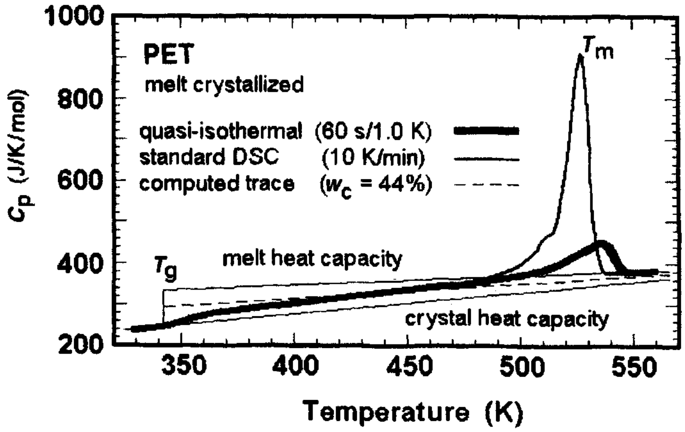

Figure 2. Experimental heat capacities of PET. The glass-transition region is marked by T_g, the melting region by T_m. The solid, thin lines indicate the data of Table 37, the dashed line indicates the crystallinity-corrected heat capacity for the semicrystalline sample, 44% crystalline, 56% amorphous. The quasi-isothermal data were measured by TMDSC at 2 K intervals with a sinusoidal temperature modulation of ± 1.0 K and a modulation period of 60 s (Ref. 35).

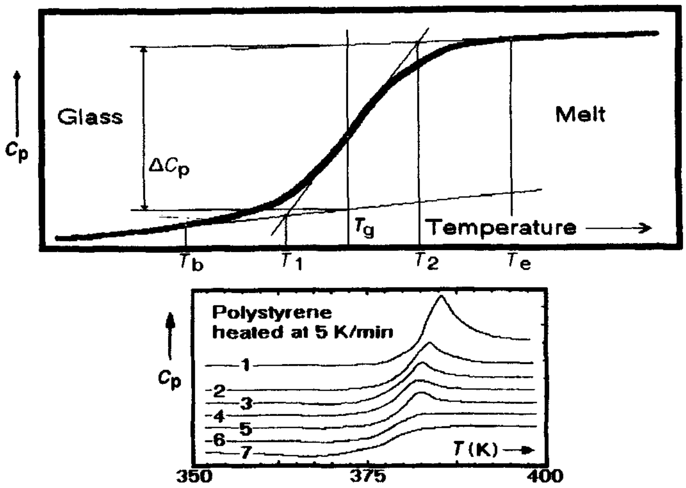

Figure 3. Schematic of the change of the heat capacity at the glass transition (top) and experimental data by DSC for polystyrene after cooling at different rates (bottom). The five characteristic temperatures of the glass transition (T_b, T_1, T_g, T_2, T_e) are marked and apply to a given time scale only. The experimental data display an enthalpy relaxation (endothermic peak if the cooling rate that sets the thermal history is less than the heating rate). The samples 1–7 were cooled at 0.084, 0.20, 0.52, 1.10, 2.50, 5.00, and 30.0 K/min, respectively.

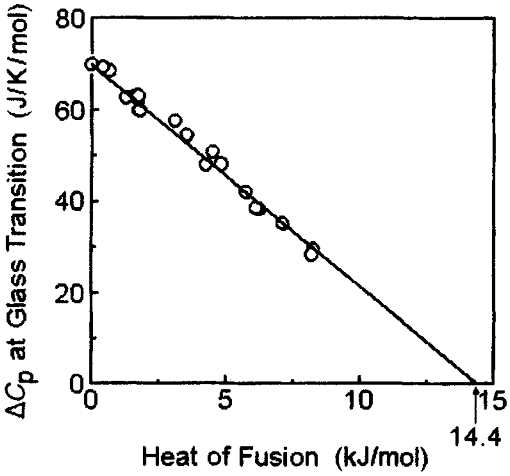

Figure 4. Change of the heat capacity of poly(oxymethylene-carbonyloxyethylene) (poly-p-dioxanone) at the glass transition with heat of fusion. (Ref. 37).

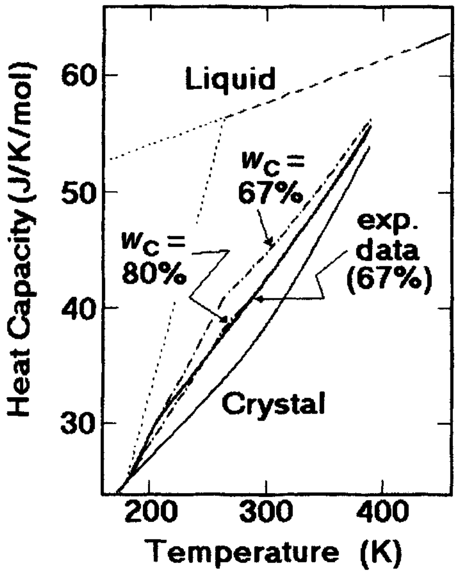

Figure 5. Effect of a rigid-amorphous fraction on the heat capacity of semicrystalline poly(oxymethylene). The measured C_p of a 67% crystalline sample (as determined from its heat of fusion) shows the heat capacity expected for an 80% crystalline sample. The 13% difference from w_c is attributed to the rigid-amorphous phase (Ref. 38).

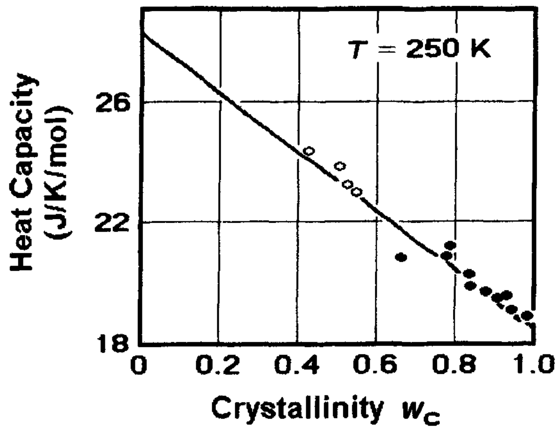

Figure 6. Heat capacity of poly(ethylene) as a function of crystallinity above the glass transition temperature ($T_g = 237$ K). The extrapolated data for zero crystallinity are entered into Table 4 for the amorphous (melt) state, for crystallinity one, for the solid.

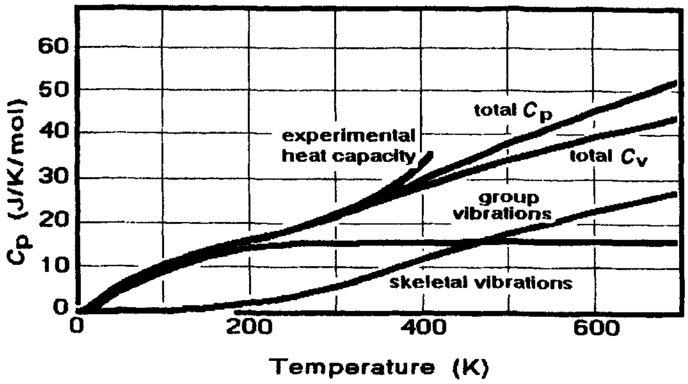

Figure 7. The contributions of skeletal and group vibrations to the heat capacity of polyethylene at constant volume, C_v. Note that, once established, the vibrational heat capacity can be extended safely beyond the range of measurement and deviations from the calculated heat capacity can be interpreted in terms of large-amplitude motion and ordering or disordering.

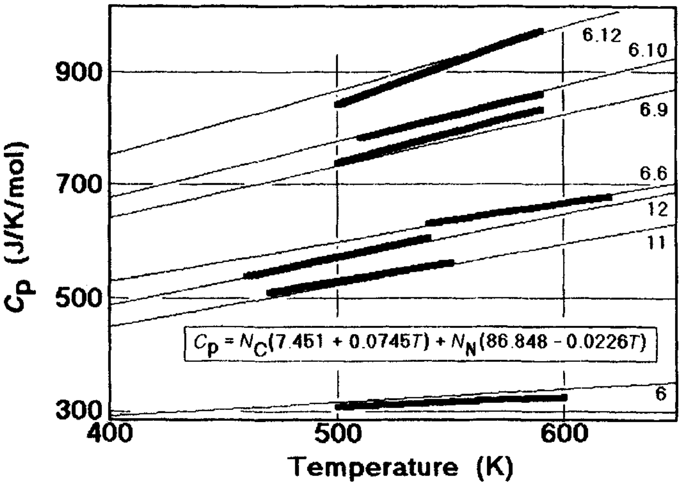

Figure 8. Heat capacity of various aliphatic nylons as measured (heavy lines) and computed from the equation (thin lines) (N_C = number of carbon atoms, N_N number of nitrogen atoms per repeating unit).

A. INTRODUCTION

1. Definition

The surface (interfacial) tension is the reversible work required to create a unit surface (interfacial) area at constant temperature (T), pressure (P), and composition (n) (1), i.e.,

$$\gamma = (\partial G/\partial A)_{T,P,n} \tag{A1}$$

where γ is the surface (interfacial) tension, G the Gibbs free energy of the system, and A the surface (interfacial) area.

The specific surface free energy f_s is the free energy per unit surface area (1), i.e.,

$$f_s = \gamma + (C_1\mu_1 + C_2\mu_2) \tag{A2}$$

where C_j is the surface concentration (the number of moles per unit area) of component j, and μ_j is the chemical potential of component j. Thus $\gamma = f_s - (C_1\mu_1 + C_2\mu_2)$, which means that the surface tension is the *excess* specific surface free energy. The *excess* means in excess of the bulk phase. This distinguishes the surface tension and the specific surface free energy (1).

2. Temperature Dependence

The surface tension of polymers, just as with small-molecule liquids, varies with temperature (1) by

$$\gamma = \gamma_0(1 - T/T_c)^{11/9} \tag{A3}$$

where γ_0 is the surface tension at $T = 0\,\text{K}$, and T_c is the critical temperature. The temperature coefficient of surface tension is thus given (1) by

$$-d\gamma/dT = (11/9)(\gamma_0/T_c)(1 - T/T_c)^{2/9} \tag{A4}$$

Since $T_c \simeq 1000\,\text{K}$ for most polymers (1), $-d\gamma/dT$ is therefore practically constant at ordinary temperatures, i.e., $T \ll T_c$.

For polymer pairs that have an upper consolute curve and an UCST (upper critical solution temperature), the interfacial tension decreases with increasing temperature and vanishes at the upper consolute temperature. This is the case for most pairs of immiscible polymers. On the other hand, for polymers that have a lower consolute curve and an LCST (lower critical solution temperature), the interfacial tension vanishes at the lower consolute point and increases with increasing temperature in the immiscible region. A few polymer pairs appear to behave this way (24).

3. Macleod's Relation

The surface tension varies with density ρ according to Macleod's relation (1)

$$\gamma = \gamma^0\rho^\beta \tag{A5}$$

where γ^0 and β are constants, independent of temperature. β is known as the Macleod's exponent, and usually has a value of 3.0–4.5 for polymers (1). Thus the surface tension is "solely" determined by the density for a given chemical composition.

γ^0 is, to a close approximation, dependent only on the chemical constitution, and is related to Sugden's parachor (1) by

$$\gamma^0 = \left(\sum P_r\right)/M_r \tag{A6}$$

where $\sum P_r$ is the parachor of the repeat unit and M_r its formula weight. Equation (A6) neglects the end group effect (1). The parachor is a group additive quantity, independent of temperature, and its values have been tabulated elsewhere (104,105).

Macleod's relation provides a number of important relationships for analyzing the effects of molecular weight, glass transition, phase transition (crystallization), and chemical constitution on surface tension, as discussed below.

4. Molecular Weight Dependence

The surface tension varies with the number-average molecular weight M_n (1) by

$$\gamma^{1/4} = \gamma_\infty^{1/4} - k_1/M_n \tag{A7}$$

where γ_∞ is the surface tension at infinite molecular weight and k_1 is a constant. Equation (A7) follows directly from Macleod's relation (1). Alternatively, an empirical relation is given (1,81) as

$$\gamma = \gamma_\infty - k_2/M_n^{2/3} \tag{A8}$$

where k_2 is a constant. Equations (A7) and (A8) fit the experimental data equally well.

Usually, the surface tension increases with increasing molecular weight. When the molecular weight is greater than about 2000–3000, the surface tension reaches within about 1 mN/m (dyne/cm) of the value at infinite molecular weight. Therefore, the effect of molecular weight may usually be neglected for polymers, except for oligomers. Several exceptions have however been observed and explained in terms of end-group effects (1,4,103).

Relationships similar to Eqs. (A7) and (A8) may be written for the interfacial tension (1,81), i.e.,

$$\gamma^{1/4} = k_0 - k_3/M_{n1} - k_4/M_{n2} \tag{A9}$$

and

$$\gamma_{12} = k_0' - k_3'/M_{n1}^{2/3} - k_4'/M_{n2}^{2/3} \tag{A10}$$

where $k_0, k_3, k_4, k_0', k_3'$, and k_4' are constants, as discussed elsewhere (1).

5. Effects of Glass and Crystal-Melt Transitions

Macleod's relation also provides relationships for the effects of glass and crystal-melt transitions. At the glass transition, the surface tension is continuous, but its temperature coefficient is discontinuous. $(d\gamma/dT)_g$ below the glass temperature, T_g, is related to $(d\gamma/dT)_r$ above T_g (1) by

$$(d\gamma/dT)_g = (\alpha_g/\alpha_r)(d\gamma/dT)_r \tag{A11}$$

where α_g is the isobaric volumetric thermal expansion coefficient in the glassy region and α_r is that in the rubbery region. Since α_g is usually smaller than α_r, the surface tension varies less with temperature in the glassy region than in the rubbery region. Since $-d\gamma/dT$ is usually small, this effect is often neglected when the temperature range of interest is small.

On the other hand, both the surface tension and its temperature coefficient are discontinuous at the crystal-melt transition. The surface tension of crystalline surface, γ_c, is related to that of amorphous surface γ_a (1) by

$$\gamma_c = (\rho_c/\rho_a)^{\beta}\gamma_a \tag{A12}$$

where ρ_c is the crystalline density, and ρ_a the amorphous density. Since $\beta = 3.0–4.5$, and usually $\rho_c > \rho_a$, the crystalline surface can have a much higher surface tension than the amorphous surface. For example, polyethylene has $\beta = 3.2$, $\rho_a = 0.855$ g/cc, $\rho_c = 1.0$ g/cc, and $\gamma_a = 35.7$ mN/m at 20°C. Thus its crystalline surface tension is given by

$$\gamma_c = (35.7)(1/0.855)^{3.2} = 58.9\,\text{mN/m}$$

Note that the value given above refers to a truly crystalline surface. Most "melt-crystallized" semicrystalline polymers, however, have amorphous surface. Only when they are nucleated in the melt against certain nucleating surfaces, or their single crystals are grown from solutions, are crystalline surfaces obtained.

6. Effect of Surface Chemical Constitution

The Macleod–Sugden equation shows that the surface tension depends on surface chemical constitution and density. Since the density is roughly a function of chemical constitution (105), it is expected that a given surface constitution will have a certain "characteristic" surface tension. Some of these values are listed in Table 1. These values should, however, be used only qualitatively.

7. Dispersion (Nonpolar) and Polar Components

The surface tension can be separated into dispersion (nonpolar) and polar components (1) i.e.,

$$\gamma = \gamma^d + \gamma^p \tag{A13}$$

where γ^d is the dispersion component (arising from dispersion-force interactions) and γ^p the polar component (arising from various dipolar and specific interactions). The polarity x^p is defined as

$$x^p = \gamma^p/\gamma \tag{A14}$$

which is independent of temperature (1), i.e.,

$$dx^p/dT = 0 \tag{A15}$$

The interfacial tension is related to the surface tension and the polarity of the two contiguous phases by the harmonic-mean equation (1),

$$\gamma_{12} = \gamma_1 + \gamma_2 - \frac{4\gamma_1^d\gamma_2^d}{\gamma_1^d + \gamma_2^d} - \frac{4\gamma_1^p\gamma_2^p}{\gamma_1^p + \gamma_2^p} \tag{A16}$$

or the geometric-mean equation (1,54,108,109),

$$\gamma_{12} = \gamma_1 + \gamma_2 - 2(\gamma_1^d\gamma_2^d)^{1/2} - 2(\gamma_1^p\gamma_2^p)^{1/2} \tag{A17}$$

where the subscripts 1 and 2 refer to the two individual phases. The harmonic-mean equation has been shown to predict the interfacial tension between polymers adequately, whereas the geometric-mean equation is often less satisfactory (1,4).

The γ^d and γ^p components can be determined either from the interfacial tension or the contact angles by using Eq. (A16), the harmonic-mean equation, or less satisfactorily by Eq. (A17), the geometric-mean equation, as discussed elsewhere (1).

The polarity may also be defined in terms of the cohesive energy density (1), i.e.,

$$x^p = (\Delta E^p/\Delta E) = (\delta^p/\delta)^2 \tag{A18}$$

where ΔE is the cohesive energy density, ΔE^p its polar component, δ the solubility parameter, and δ^p its polar component. The polarity values determined from interfacial properties have been found to agree with those determined from cohesive energy densities for a number of polymers (1). It should be cautioned, however, that Eq. (A14) defines the surface polarity, while Eq. (A18) defines the bulk polarity. These two values may not be the same, if the polymer has sufficiently long surface-active segments, which tend to preferentially adsorb on the surfaces.

B. TABLES

Table 1 lists typical values of surface tension for some surface chemical constitutions.

Table 2 lists the surface tension, its temperature coefficient, polarity, and Macleod's exponent for amorphous surfaces. The surface tension for crystalline surface may be calculated from the amorphous value by using the Macleod's exponent. All data were obtained by direct reversible measurements in the melt. The values for the solid were obtained by extrapolation from the melts. These are the most reliable and preferred. On the other hand, some values were obtained by the contact angle method. These are denoted with the symbol (c). The two values usually agree well.

Table 3 lists the interfacial tension and its temperature coefficient for amorphous interfaces. All data were obtained by direct reversible measurements in the melt. The values for the solid were obtained by extrapolation from the melt and have been shown to be reliable. The interfacial tension

References page VI - 540

may also be estimated from the surface tension and the polarity of the two phases by using the harmonic-mean equation (Eq. (A16)).

A. INTRODUCTION

The transmission of molecules through polymer films is named "permeability". There are many dimensions and units found in the literature for the general expression "permeability". In this paper the permeability coefficient is used. It has the dimension

$$P = \frac{(\text{quantity of permeant}) \times (\text{film thickness})}{(\text{area}) \times (\text{time}) \times (\text{pressure drop across the film})}$$

and is the best definition for permeability.

The permeability coefficient, in a strict sense, is not only a function of the chemical structure of the polymer. It also varies with the morphology of the polymer and depends on many physical factors such as density, crystallinity, and orientation. However, the chemical structure of a polymer can be considered to be the predominant factor which controls the magnitude of the permeability coefficient.

The following general trends in permeability, as related to some influencing factors, may be useful for the proper interpretation of the tables:

Density can be regarded as a measure of the free volume between the molecules of the polymer structure. In general, the higher the density, the lower is the permeability.

Crystallinity of a semicrystalline polymer reduces the permeability significantly compared to the value of the corresponding amorphous polymer; i.e., the higher the degree of crystallinity, the lower the permeability. The crystallinity and the density of a polymer are strongly related. The higher the crystallinity the higher is the density of a given polymer.

Molecular mass of a polymer has been found to have little effect on the permeability of polymers, except at a very low range of molecular masses.

Orientation of polymer molecules reduces the permeability.

Crosslinking decreases the permeability, especially for higher degrees of crosslinking and for large molecular size permeants.

The method and degree of vulcanization has a significant effect on the permeability of elastomers.

Plasticizers increase the permeability.

Humidity increases the permeability of some hydrophilic polymers.

Liquid permeants have the same permeabilities as their corresponding saturated vapors, though higher permeabilities may occur especially if parts of the polymer are being dissolved.

Solution cast films have variable permeabilities depending upon the kind of solvent used and the drying technique. Poor solvents tend to yield films of higher permeability.

Fillers, usually inorganic fillers, decrease the permeability; however, the effect is complicated by the type, shape, and amount of filler and its interaction with the polymer.

Thickness of film does not, in principle, affect the permeability coefficient, the diffusion coefficient, and the solubility coefficient. In practice, different values may be obtained from films of variable thickness, which in turn may be due to differences in drawing, orientation, and crystallinity.

If a permeant does not interact with the polymer under investigation, the permeability coefficient is characteristic for the permeant–polymer system. This is the case with the permeation of many gases, such as H_2, He, N_2, O_2, and CO_2, through many polymers. On the other hand, if a permeant interacts with the polymer, the permeation coefficient is no longer a constant, and may depend on the special conditions of the measurement and the history of the polymer film. In such cases, a single value of the permeability coefficient does not represent the characteristic permeability of the polymer, and it is necessary to know the dependency of the permeability coefficient on all possible variables in order to obtain the complete profile of the permeability of the polymer.

In these cases, the transmission rate, which has the dimension

$$Q = \frac{(\text{quantity of permeant})}{(\text{area}) \times (\text{time})}$$

is often used for practical purposes. Since the transmission rate, Q, includes neither the pressure of the permeant nor the thickness of the polymer in its dimension, it is necessary to know either the pressure or the concentration of the permeant and the thickness of the polymer under the conditions of measurement.

For both P and Q, the quantity of permeant can be expressed by mass, moles, or gaseous volume at standard temperature and pressure. These can readily be converted from one unit into another.

The preferred SI unit of the permeability coefficient used in this book is

$$\text{unit of } P : \frac{\text{cm}^3(273.15\,\text{K};\ 1.013 \times 10^5\,\text{Pa}) \times \text{cm}}{\text{cm}^3 \times \text{s} \times \text{Pa}}$$

where (273.15 K; 1.013×10^5 Pa) means standard temperature and pressure (STP). Therefore permeability coefficients given in this paper are in the range of 10^{-11} – $10^{-16}\,\text{cm}^3 \times \text{cm/cm}^2 \times \text{s} \times \text{Pa}$ for many polymers and permeants.

The mostly used units and their conversion factors are listed in Table B.

The permeation of molecules through flawless polymers occurs by the steps of dissolution of a permeant in the polymer and diffusion of the dissolved permeant. The product of the diffusion coefficient D and the solubility coefficient S is referred to as the permeability coefficient.

$$P = D \times S$$

Units of D and S used in these tables are

$$\text{unit of } D : \frac{\text{cm}^2}{\text{s}}$$

$$\text{unit of } S : \frac{\text{cm}^2(273.15\,\text{K};\ 1.013 \times 10^5\,\text{Pa})}{\text{cm}^3 \times \text{Pa}}$$

The solubility coefficients cited in the following tables are often calculated by

$$S = \frac{P}{D}$$

The temperature dependence of the permeability coefficient P, the diffusion coefficient D, and the solubility coefficient S can be represented by

$$P = P_0 \times \exp(-E_P/RT)$$
$$D = D_0 \times \exp(-E_D/RT)$$

and

$$S = S_0 \times \exp(-E_S/RT)$$

Consequently

$$E_P = E_D + E_S$$

where E_P is the activation energy of permeation, E_D the activation energy of diffusion, and E_S the heat of solution. P_0, D_0, and S_0 are the pre-exponential factors. Values of E_P, E_D, and E_S are given in kJ/mol in the following tables. R is the gas constant (8.3144×10^{-3} kJ/K mol); T is the temperature in K. In the following tables the temperature range is given in which P_0, E_P, E_D, and E_S are relevant, as far as the authors have reported it. The permeability coefficient can be determined for a given temperature by means of the pre-exponential factor P_0 and the activation energy of permeation E_P. In the following tables, permeability, diffusion, and solubility coefficients are listed for many polymers. The pre-exponential factor P_0, the activation energy of permeation E_P, the activation energy of diffusion E_D, and the heat of solution E_S are also given. The pre-exponential factors D_0 and S_0 can be determined by the following equations:

$$D_0 = D \times \exp(E_D/RT)$$
$$S_0 = S \times \exp(E_S/RT)$$

C. TABLES

TABLE 1. PERMEABILITY COEFFICIENTS, DIFFUSION COEFFICIENTS, AND SOLUBILITY COEFFICIENTS OF POLYMERS

Units used in the tables are as follows: P, P_0 in cm^3 (273.15 K; 1.013×10^5 Pa) × cm/(cm^2 × s × Pa); D in cm^2/s; S in cm^3(273.15 K; 1.013×10^5 Pa)/(cm^3 × Pa); E_p, E_D, E_S in kJ/mol; T in °C; (273.15 K; 1.013×10^5 Pa) means standard temperature and pressure (STP).

A. INTRODUCTION

The refractive indices of polymers provide fundamental physical property information that can be used in characterization, processing, and usage analyses. In-depth description of refractive indices based on classic electromagnetic theory can be found in basic texts (1,2). The purpose of this monograph is to provide a convenient reference of values and some general remarks in approximating and utilizing refractive indices of polymers.

The refractive index, reported as the velocity of light in a vacuum relative to the velocity in the polymer, depends on the wavelength of light. All values reported in this chapter refer to the sodium spectral line $\lambda = 5893$Å, referred to as n_D in this literature. However, for simplicity, the subscript D is omitted here in the subsequent discussion and tables. In general, it should be kept in mind that for any polymer, the refractive index represents an average property of its aggregate state (3,4). Orientation, conformation, as well as phase changes may all contribute to variations in the index of refraction of a polymer with a given chemical structure. Thus, the refractive index may not be expected to be equal along all axes of the molecule (5). Consequently, the measured refractive index is an average value, with contributions from the refractions of the molecule's different chemical bonds. It can be shown from classic electromagnetic theory that the square of the refractive index (n^2) is the appropriate form to use in molecular descriptions of refractive indices since it is related to the dielectric tensor, having a magnitude as well as a directional description (1,4). However, since $1.3 < n < 1.7$ for most polymers, correlations proposed for n^2 almost always find a simplified version with n (3,4).

B. MOLAR REFRACTION

The molar refraction of a substance, a product of its refractive index, molecular weight, and density, may be assumed to be a fundamental physical property of materials (1). Furthermore, the molar refraction may be treated (as established by Denbigh) as the sum of the bond refractions that make up the molecule (6). These two postulates make possible, the calculation of the refractive indices of polymers almost from first principles (7,8). Two useful relations for the molar refraction, R, are provided here (1): The Lorentz–Lorentz equation

$$R = \frac{n^2 - 1}{n^2 + 2}\frac{M}{\rho} \tag{B1}$$

The Gladstone–Dale equation

$$R = (n - 1)\frac{M}{\rho} \tag{B2}$$

where ρ is the density of the polymer and M its molecular weight. The molar refraction may be assumed to be the sum of the refractions of all the bonds or groups that make up the polymer system, i.e., $R = \sum_i R_i$ (6,7). Chemical group refractivities that can be used in the calculation of refractive index of polymers have been recently summarized by Van Krevelen (8). For example, for a homopolymer whose repeat monomer unit refractivity, R_M, is known, with $R = \mathrm{DP}\, R_M$ (where DP is the degree of polymerization) and $M = \mathrm{DP}\, M_M$ (M_M = molecular weight of the monomer unit), then the refractive index of the polymer by the Gladstone–Dale expression (Eq. B2) becomes

$$\mathrm{DP}\, R_M = (n - 1)\frac{\mathrm{DP}\, M_M}{\rho} \quad \text{or} \quad n = 1 + \frac{M_m}{R_m}\rho \tag{B3}$$

This may be calculated only from a knowledge of the monomer unit molar refraction and molecular weight. The

use of bond or group refractions in the calculation of refractive indices of polymers has been demonstrated to be in good agreement with the measured values for homogeneous, unoriented polymers (8).

C. REFRACTIVE INDICES OF HETEROGENEOUS POLYMERS

For polymeric systems whose phase dimensions are below the wavelength of the incident light, the application of the Maxwell relations is valid and the refractive index of the polymer may be expressed in terms of the dielectric constants of the constituent phases (1). The dielectric constant, k, is equivalent to the square of the refractive index ($k = n^2$), and it can be demonstrated that an upper bound of the refractive index of the polymer may be obtained as the sum of dielectric constants of the constituent phases (4,5):

$$n^2 = \sum_i v_i n_i^2 \qquad \text{(C1)}$$

where n_i and $v_i(\sum v_i = 1)$ are the refractive indices and volume fractions of the constituent phases of the components that make up the polymer. Similarly, the lower bound of a polymer's refractive index may be computed as the sum of the inverse of the dielectric constants of the constituent phases (4):

$$\frac{1}{n^2} = \sum_i \frac{v_i}{n_i^2} \qquad \text{(C2)}$$

For most heterogeneous polymers, however, whose constituent refractive indices differ by less than 0.2, i.e., $(n_i - n_j \leq 0.2)$, the refractive index of the polymer may be computed by the Gladstone–Dale relation, assuming additivity of the refractive indices of the constituent phases (3,4):

$$n = \sum_i v_i n_i \qquad \text{(C3)}$$

The calculation methods described above may be used for multiphase polymers such as blends, block or graft copolymers, composites, and semicrystalline polymers.

D. OPTICAL ANISOTROPY*

Small as well as long polymer molecules exhibit different refractive indices parallel and perpendicular to the molecular chain axis. Thus, all polymers should be viewed as intrinsically anisotropic. The degree of anisotropy exhibited in bulk property behavior will depend on the molecular orientation imposed by deformation during processing or testing. Only in its unoriented state can a polymer be characterized by a single refractive index, since its optical properties will be identical in all directions. Consequently, optical anisotropy is one of the simplest and often used methods of studying orientation in polymers (5). By polarizing light in a specific direction, the refractive index of a polymer can be measured in that direction. Consequently, all three principal refractive indices of a polymer, n_x, n_y, n_z, corresponding to an x, y, and z direction, can be measured. For example, a refractometer fitted with a polarized eye piece has been successfully used to measure refractive indices along the major axes of polymer films (9). The average refractive indices of a polymer may be computed from the refractive indices along the axes of the polymer:

$$n = (n_x + n_y + n_z)/3 \qquad \text{(D1)}$$

For the unoriented (isotropic) condition ($n_x = n_y = n_z$), a single value of the refractive index provides a unique optical description ($n = n_x = n_y = n_z$). For oriented polymers, the difference in refractive indices along two orthogonal directions can be used as the measure of optical anisotropy and, consequently, orientation of the polymer. The difference in refractive indices is defined as the birefringence or double refraction. According to Stein (5), there are three birefringences, Δ_{ij}'s that may be defined for a cartesian coordinate system, with two of them being independent. They are

$$\Delta n_{xy} = n_x - n_y \qquad \text{(D2)}$$

$$\Delta n_{xz} = n_x - n_z \qquad \text{(D3)}$$

$$\Delta n_{yz} = n_y - n_z = \Delta n_{xz} - \Delta n_{xy} \qquad \text{(D4)}$$

For a polymer exhibiting transverse isotropic symmetry, as in the case of uniaxial orientation (i.e., deformation along one axis), a single birefringence is enough to characterize orientation and anisotropy. For example, for a polymer oriented uniaxially along the x direction, $\Delta n_{xy} = \Delta n_{xz}$ and $\Delta n_{yz} = 0$. For a fully oriented polymer, where the molecular chain axis is aligned with the deformation axis (perfect orientation) a limiting value of birefringence is reached, which is defined as the intrinsic birefringence of the polymer (10,11) and denoted as

$$\Delta n_{xz} = n_{xy}^0 f \qquad \text{(D5)}$$

where f is the Hermans orientation function

$$f = \frac{\overline{3\cos^2\theta - 1}}{2} \qquad \text{(D6)}$$

defined on the average angle θ that the molecular chain axis makes with the deformation axis. The Hermans orientation function (D6), $-1/2 \leq f \leq 1$ assumes the value of $-1/2$ when the molecular chain axis is perpendicular to the deformation axis; 0 for random orientation (isotropy); and -1 for perfect alignment of the chains with the deforma-

*See also corresponding table in this Handbook.

tion axis. The use of the refractive index in the calculation of birefringence, rather than the difference of some function of the dielectric constant (n^2 or $1/n^2$), is an approximation to optical anisotropy. Thus, if the birefringence is used as a measure of orientation, as was proposed by Stein, form effects should be considered (5,7,11)

$$\Delta n_{xz} = n_{xy} f + \Delta_{\text{form}} \tag{D7}$$

The importance of form may be estimated from bond polarizabilities for a given polymer (4,7). Thus, to characterize completely the optical properties of a given polymer, its average refractive index as well as the intrinsic and form birefringences must be specified. To date, very few polymers have been optically characterized in such detail. However, as more refined and specific performance is demanded from polymers, this information is forthcoming. In order to demonstrate the usefulness of complete characterization and to summarize the data available till date, an example for semicrystalline polymers is provided, along with a table showing reported values (for a few polymers) of average refractive indices and intrinsic birefringences.

E. APPLICATIONS

Using Eq. (B2), the unoriented refractive index of a semicrystalline polymer may be calculated from a knowledge of its intrinsic crystalline and noncrystalline densities and refractive indices. First, the volume fraction crystallinity, v_{cr}, is calculated from the densities:

$$v_{\text{cr}} = \frac{\rho - \rho_{\text{nc}}}{\rho_{\text{cr}} - \rho_{\text{nc}}} \tag{E1}$$

where ρ is the bulk measured density, and ρ_{cr} and ρ_{nc} are the crystalline and noncrystalline densities. Then the average refractive index is

$$n = v_{\text{cr}} n_{\text{cr}} + (1 - v_{\text{cr}}) n_{\text{nc}} \tag{E2}$$

From Stein's equation of birefringence additivity (neglecting form birefringence) (5,11)

$$\Delta n_{xy} = v_{\text{cr}} \Delta n^0_{xy_{\text{cr}}} f_{\text{cr}} + (1 - v_{\text{cr}}) \Delta n^0_{xy_{\text{nc}}} f_{\text{nc}} \tag{E3}$$

where $\Delta n^0_{xy_{\text{cr}}}$ and $\Delta n^0_{xy_{\text{nc}}}$ are the crystalline and noncrystalline intrinsic birefringences, and f_{cr} and f_{nc} are the corresponding crystalline and noncrystalline Hermans orientation functions.

If the intrinsic properties of a semicrystalline polymer are known, Eq. (E2) can be used to calculate the volume fraction crystallinity by simply measuring the polymer's refractive index, while Eq. (E3) can be used to obtain the value of the noncrystalline orientation function by measuring birefringence and crystalline orientation by an independent technique [e.g., wide angle X-ray (5)]. For a single-phase polymer like polystyrene, the orientation function can be directly calculated from the measured birefringence value and the known intrinsic birefringence:

$$f = \frac{\Delta n_{xy}}{\Delta n^0_{xy}} \tag{E4}$$

Once these quantities are known, it becomes possible to completely characterize and predict the optical anisotropy of a given polymer from its unoriented to its oriented state (3,4).

Table 1 is provided to demonstrate that such basic optical parameters may be obtained from the literature (3,4,9,12–16). The recognition of polymers as anisotropic heterogeneous systems continues to expand and their refractive indices provide useful insight into their process–structure–property interrelations (18–20). It is hoped that continuous investigations in existing as well as new polymers will expand this compilation.

Finally, Table 2 provides average refractive indices of polymers arranged in order of increasing values, while Table 3 provides the same list in alphabetical order. Some additional values from the recent literature (21–23) have been added to the earlier compilation (17) to form the material for the present edition.

TABLE 1. INTRINSIC OPTICAL PROPERTIES OF SELECTED POLYMERS

Polymer	Crystalline density (ρ_{cr})	Noncrystalline density (ρ_{nc})	Phase average refractive indices		Intrinsic birefringence ($\times 10^3$)	
			n_{cr}	n_{nc}	Δn^0_{cr}	Δn^0_{nc}
Poly(propylene)	0.936	0.850	1.519–1.524	1.471	23–30	60–86

TABLE 2. *cont'd*

Polymer	*n*	*T* (°C)
Poly(vinylcarbazole)	1.683	20
Naphthalene–formaldehyde resin	1.696	
Phenol–formaldehyde resin	1.70	
Poly(pentabromophenyl methacrylate)	1.71	

[a]Temperature in °C are listed when available. In general, *n* may be assumed to decrease with increasing temperature. Approximate change may be calculated as $dn/dT = -1 \times 10^{-4}$ to 2×10^{-4}/°C for glassy polymers and $dn/dT = -3 \times 10^{-4}$ to 5×10^{-4}/°C for amorphous unoriented polymers above the glass transition.

A. INTRODUCTION

1. General Comments

The data on radiation resistance have been compiled mainly for practical polymer materials that have been classified into four groups: thermoplastics, elastomers, all aromatic polymers, and composite materials. The values of radiation resistance were determined by the change in mechanical properties. Radiation-induced degradation of polymer materials depends greatly on the irradiation conditions, as indicated in the tables; hence, the reader is advised to use these data with caution, considering all the factors.

2. Criterion for Radiation Resistance

Radiation resistance is characterized by the half-value-dose of significant changes in mechanical properties. For elastomers and thermoplastics, with large ultimate elongation by tensile test, the resistance is characterized by 100% elongation at break. The half-value-dose means the absorbed dose that reduces a property to 50% of its initial value under defined environments. The SI unit gray (Gy; 1 Gy = 1 J/kg = 100 rad) is used, and values in tables are in units of MGy (10^6 Gy) when there is no notation. In cases where the absorbed dose in the experiment was terminated before reaching the criterion, the dose is given with the sign ">".

The properties can be affected differently, therefore more than one relevant property should be considered. In most cases, the properties used to characterize radiation resistance are the elongation at break for elastomers and flexible plastics, and the flexural strength for rigid plastics and composite materials. However, the elongation at break sometimes increases with elastomers deterioration, but in that case, the strength decreases greatly.

3. Factors of Influence and their Consideration in Tables

Radiation resistance depends on polymer formulation as well as on the conditions of radiation exposure, such as the environmental atmosphere, temperature, dose rate, mechanical stress, etc. The most effective factor is the oxidation induced by radiation. Radiation resistance is indicated in two categories, with and without oxidation, together with the irradiation conditions employed.

3.1. Type of Polymer and Formulation The polymer samples reported were generally formulated by mixing with chemical agents, such as of stabilizers and fillers. Elastomers were normally crosslinked. The formulation and/or crosslinking have many variations for a given type of polymer. The formulation is determined by the suppliers based on the application (which may need, improve the mechanical or thermal properties), and the contents are usually not disclosed. Radiation resistance is influenced by formulation and crosslinking. In general, radiation resistance can be increased with inorganic fillers, with good adhesion between the polymer and reinforcing fillers, with

antioxidants, and with aromatic compounds. Organic fillers usually decrease radiation resistance. Some of the aromatic polymers reported may contain fillers of glass or carbon fibers.

The first column of the tables give the polymer name, along with the formulation or cross-linking. The second column gives the form of the test sample: either sheets (formed by heat press) or films (formed by extrusion or inflation), and their thickness (in mm).

3.2. Type of Radiation and Dosimetry The overall radiation effect does not depend on the type of radiation (such as X rays, gamma rays, electron beams, nuclear reactor irradiation, or other accelerated particle radiation), but only on the absorbed dose. There are some uncertainties about the given dose, especially to different types of radiation. In the following tables, the accuracy of the dose is estimated to be ±10% for gamma-rays and ±20% for electron beams or accelerated particles.

3.3. Dose Rate and the Atmosphere In an inert gas atmosphere or under vacuum, the dependence of dose rate on polymeric degradation is negligible at ambient temperature (1). If the other stresses, such as thermal degradation or light exposure, are eliminated during irradiation, the degradation should depend on the accumulated dose. If oxygen is present, the induced oxidation will decrease radiation resistance. The overall oxidation is determined by the rate of oxygen consumption by radiation-induced oxidation in the polymer matrix, and by the rate of oxygen supply into the matrix. The thickness of the polymer oxidation layer (L_{ox}) is a function of radiation dose rate (I), oxygen partial pressure (P_{o_2}) at one atmosphere total pressure, oxygen permeability coefficient (P_c) into the polymer matrix, and oxygen consumption factor (Φ), and is given by the following equation. (Ref. 2,3).

$$L_{ox} = (P_c P_{o_2} / I \Phi)^{1/2} \qquad (1)$$

When the test material is a thick sheet, the oxidation layer occurs only at the surface, and the inside is not oxidized. The oxidation layer increases with decreasing dose rate. For most polymers, the degradation is more progressive with oxidation than without it. The dose rate affects the ratio of oxidation layer to material thickness. The degradation with oxidation can be observed by irradiation of a thin film; here, oxidation proceeds throughout the film. Oxidation throughout a thick film requires irradiation with oxygen under pressure rather than decreasing the dose rate (4). In the following tables, radiation resistance with oxidation implies that oxidation takes place throughout the material.

The other dose-rate dependent degradation, chain-reaction oxidation, has been reported at low dose-rate irradiations over long time periods. We believe that it is difficult to distinguish these chain reactions from thermal oxidation. In the tables, the data for very low dose rate have been excluded.

3.4. Temperature The irradiation temperature is ambient temperature, i.e. about 20–30 °C. The data for low-temperature irradiation is listed for few materials. Several experiments performed at higher irradiation temperatures are also listed. As the resistance depends on irradiation temperature, it is supposed that chemical reactions increase greatly due to the increased molecular motions during irradiation.

3.5. Other Stresses The tables do not consider mechanical stress and deformation during irradiation. These factors can have a large influence on degradation.

B. LIST OF SYMBOLS USED

σ	Tensile strength at break (ultimate strength)
$\sigma_{1/2}$	Half of tensile strength at break
ε	Elongation at break (ultimate elongation)
$\varepsilon_{1/2}$	Half of elongation at break
$\varepsilon_{100\%}$	100% of elongation at break
σ_F	Flexural strength
$\sigma_{F1/2}$	Half of flexural strength
IL	Inter Lamella Shear Strength (ILSS)
$IL_{1/2}$	Half of ILSS
γ	^{60}Co- γ-rays
EB	Electron beams, ( ) energy
n	Neutron, ( ) energy
H^+	Proton, ( ) energy
RT	Room temperature
Vac	Vaccum (including seal after vacuum)
Air	Air atmosphere
He	Helium-gas atmosphere
N_2	Nitrogen-gas atmosphere
O_2	Oxygen gas, ( ) indicates pressure

C. TABLES OF RADIATION RESISTANCE

TABLE 1. THERMOPLASTICS

				Radiation resistance

A. INTRODUCTION

Pressure–volume–temperature (*PVT*) behavior of polymeric materials are important both from the practical and scientific viewpoint. On the practical side, a general knowledge of *PVT* properties are often required for processing polymers. On the scientific side, *PVT* properties are often required as input information on molecular models of polymer solutions. Information on molecular packing is also reflected in *PVT* properties. Numerous equations of state (EOS) have been developed to describe polymers. One can divide them into two categories: phenomenological and molecular.

Equations of state in the first category are for the empirical representation of volumetric data. The majority of equations in this group are the so-called isothermal compressibility equations (1–4). The purely empirical, original Tait equation and its modification by Tammon have been almost exclusively used for organics, including polymers (2,3,5,6).

Sanchez et al. re-examined polymer bulk data in a rigorous classical thermodynamic analysis (7,8). A new principle of temperature–pressure (T–P) superposition of compression response was found. Stated briefly, a dimensionless pressure variable is used to superpose compression data as a function of temperature into a universal curve. The governing parameter of compression is the first pressure coefficient $B_1(= \partial B/\partial P)_{P=0}$, of the bulk modulus B. It is related to the asymmetry of the free energy around its minimum, between dilation and compression. For polymers, B_1 is around 10, and universal. A new isothermal equation of state was formulated through a Padé analysis of the pressure dependence of the bulk modulus (8). Both the Tait and the Padé equations describe almost perfectly the isothermal pressure dependence of volume. Both can be used to smoothen experimental *PVT* data.

Equations of state in the second category arise from molecular models and the development of a proper partition function (9). Most earlier works on this group are based on the lattice or quasi-lattice description of a fluid. Three types of models have played a dominant role in the past several decades. These are the cell, hole, and lattice fluid models.

In Prigogine's cell model (10–12), any monomer is considered to be enclosed by the cell of surrounding molecules. The configurational potential is separated into the mean potential (between the center of the cell and surroundings), and the cell potential (generated by the movement of the central monomer within the cell). The cell potential was further simplified to be athermal. The Simha–Somcynsky theory (13) incorporated the lattice imperfection (hole) into the simple cell model by Prigogine et al. Flory et al. (14) borrowed some ideas from the cell model (separation of internal and external degrees of freedom) but used a Tonk's gas-type description for the repulsive part of the intermolecular potential. Unlike the cell model, the molecules are not localized in space, and a van der Waals mean field energy is employed. Meanwhile, the lattice fluid model (15,16) introduces lattice vacancies as pseudo-solvent molecules into the incompressible Flory–Huggins model. In this model, an incompressible polymer solution is converted into a compressible bulk polymer liquid.

All theoretical equations of state suggest a corresponding states behavior of polymer PVT properties that requires three scaling parameters such as characteristic temperature (T^*), pressure (P^*), and volume (V^*).

The derivation of the partition function can in principle be done in continuum space. This approach yields the so called integral equation theory (9). The self consistent integral equations of the interparticle distribution functions are to be determined. For the simplest hard sphere chains, several analytical equations of state were suggested by Chiew (17–22), Wertheim (23–27) and Chapman (28,29). Chiew's equation of state is based on Baxter's solution of the Percus–Yevick integral equation for the adhesive hard sphere (AHS) system. The AHS has a strong, but extremely short ranged attractive interaction at its surface. This peculiar interaction is treated as chemical bonds. Wertheim and Chapmann considered this adhesive attraction as a perturbation to the hard sphere potential in the framework of graph theory. A different and unique work on this subject was performed by Hall and coworkers (30) without recourse to integral equation theory. A particle insertion method was generalized to hard chains in continuum space.

To apply these continuum models to real systems, an energetic contribution to pressure should be added on the basis of a perturbation theory. In the simplest approximation a mean field (van der Waals) energy is added (28,31). The incorporation of the energy term turns these off-lattice models into 3-parameter (V^*, T^*, P^*) corresponding states models.

There are empirical or semiempirical equations of state that can be included partly in the two categories. The Sanchez–Cho (32), and the Hartmann–Haque (33) equations are considered the most important in applications. These two equations of state also suggest a corresponding states behavior.

This article only deals with liquid data (above T_g or T_m). The mathematical expression of the liquid PVT data with either the Padé or the Tait equations are tabulated here for extracting the 3 characteristic parameters (V^*, T^*, P^*) for given corresponding states equations of state.

The characteristic parameters are essential in the application of a given equation of state to real systems. We present, therefore, a compendium of such parameters for the 3-parameter equations of state described above. These parameters have their own physical meaning according to theories at hand. However, these are treated as adjustable parameters in a general nonlinear regression routine to best represent the smoothed experimental values regenerated from the Sanchez–Cho or the Tait equations. We used the volume data over the whole experimental T–P range. All model parameters are determined from the same data sets.

B. ISOTHERMAL COMPRESSIBILITY EQUATIONS

The recently found principle of temperature–pressure (T–P) superposition (7,8) implies that the $\ln(V/V_0)$, is a function of the scaled pressure, P/B_0, as is compression, given below:

$$\ln(V/V_0) = f\left(\frac{P}{B_0}\right) = -\frac{P}{B_0} + \frac{B_1}{2!}\left(\frac{P}{B_0}\right)^2 - \frac{1}{3!}(2B_1^2 - B_0B_2)\left(\frac{P}{B_0}\right)^3 + \cdots \quad \text{(A1)}$$

where V_0 and B_0 are volume and the bulk modulus at zero pressure, respectively. The right hand side of Eq. (A1) is a rigorous power series expression of $\ln(V/V_0)$. The additional contributing numbers $B_i (i \geq 0)$ are the coefficients in the series expansion of the bulk modulus B in pressure:

$$B = B_0 + B_1P + \frac{1}{2}B_2P^2 + \cdots \quad \text{(A2)}$$

A tractable approximation to the infinite series in Eq. (A1) was suggested by Sanchez et al. They utilized the empirical observation that the bulk modulus B in Eq. (A2) is linear in pressure to high pressures. Expecting that the modulus B diverges as $P^{\omega}(\omega < 1)$, a Padé analysis and the successive integration of B yielded the Padé equation (8) given below:

$$\ln(V/V_0) = \frac{\omega}{(1-\omega)B_1}\left[1 - \left(1 + \frac{B_1}{\omega}\frac{P}{B_0}\right)^{1-\omega}\right] \quad \text{(A3)}$$

where the curvature parameter, ω, is defined as

$$\omega = B_1^2/(B_1^2 - B_0B_2) \quad \text{(A4)}$$

A pair of universal values of B_1 and ω ($B_1 = 10.2$, $\omega = 0.9$) is observed to be excellent in correlating the bulk volumetric data of various polymers.

The historically well known Tait equation falls into the general statement of the T–P superposition in Eq. (A1):

$$\ln(V/V_0) = \ln\left[1 - C\ln\left(1 + \frac{1}{C}\frac{P}{B_0}\right)\right] \qquad \text{(A5)}$$

where C is universally 0.0894 (Cutler's constant). Equation (A5) is the modified version, by Tammon, of the original Tait equation, which was empirically formulated for water. One should notice that the product, CB_0, comprises the so-called Tait parameter in the literature. Equations (A3) and (A5) yield an accurate representation (within experimental error) of isothermal, volume–pressure relationships.

The zero pressure volume, V_0, and modulus, B_0, are additionally required to complete Eqs. (A3) and (A5). The compilation of these parameters are shown in Table 1. In this table, the abbreviation of polymer names are used. The explanation of the abbreviated names and experimental T–P range are listed in Table 2. Several types of fitting functions are used for V_0. Typically used are the polynomial and exponential expressions. For the bulk modulus, the exponential dependence on temperature is almost exclusively used. Some other polymer PVT data that are not used to obtain the characteristic parameters can be found in the literature, including blends and liquid crystalline polymers (38,50,55,59–67).

C. EMPIRICAL OR SEMIEMPIRICAL 3-PARAMETER EQUATIONS OF STATE

Equations in this section are in between the compressibility equations and succeeding model equations of state: (a) they are formulated on the basis of phenomenological arguments; (b) they suggest a corresponding behavior or a universal relationship between dimensionless V, T and P. The Sanchez–Cho and the Hartmann–Haque equations of state are considered the most important equations in this category.

Sanchez–Cho (S–C) Equation of State The Sanchez–Cho equation of state (32) was formulated by combining the empirically observed temperature dependence of the zero pressure volume V_0 and modulus B_0 with the isothermal Padé equation, Eq. (A3):

$$\tilde{V} = \frac{1}{(1-\tilde{T})}\exp\left[\frac{\omega}{(1-\omega)B_1}\left\{1 - \left(1 + \frac{B_1\tilde{P}e^{\tilde{b}\tilde{T}}}{\omega}\right)^{1-\omega}\right\}\right] \qquad \text{(A6)}$$

where the required universal numbers are $B_1 = 10.2$, $\omega = 0.9$, and $\tilde{b} = 9$. The dimensionless variables are defined as:

$$\tilde{V} \equiv V/V^*, \tilde{T} \equiv T/T^*, \tilde{P} \equiv P/P^* \qquad \text{(A7)}$$

The V^* and P^* are related to the van der Waals volume and cohesive energy density (32). The Sanchez-Cho equation provides volume as an explicit function of temperature and pressure, as is shown in Eq. (A6). Equation (A6) is to date the most accurate 3-parameter equation of state. The comparison of Eq. (A6) with the empirical Tait or Padé equation over the whole experimental T–P range gives the average deviation in volume less than 0.0004 cm^3/g. The Sanchez–Cho equation is useful in extrapolating data to high pressures and investigating the negative pressure region. The three characteristic parameters for the Sanchez–Cho equation are given in Table 4.

Hartmann–Haque (H–H) Equation of State The Hartmann–Haque equation of state (33) has the following functional form:

$$\tilde{P}\tilde{V} = \tilde{T}^{3/2} - \ln\tilde{V} \qquad \text{(A8)}$$

where the dimensionless variables $\tilde{P}, \tilde{V}, \tilde{T}$ are defined as in Eq. (A7). The P^* is identified as the isothermal bulk modulus extrapolated to zero temperature and pressure. The zero pressure isobar in Eq. (A8) originates in the Simha–Somcynsky hole model (13) in the next section. The three characteristic parameters for the Hartmann–Haque equation are given in Table 5. The average deviation between Eq. (A8) and regenerated bulk PVT data (data smoothed using the Tait Eq.) is 0.0009 cm^3/g or more than a factor of 2 worse than the S–C equation.

D. LATTICE OR QUASI LATTICE MODELS

The most frequently used model equations of state based on the lattice or quasi lattice phase space are visited in this section. These are various cell models of Prigogine et al., the hole model, and the lattice fluid model. The common feature of the models in this section is the separation of pressure into the thermal (P_{th}) and internal (P_i) pressures:

$$\frac{\tilde{P}}{\tilde{T}} = \frac{\tilde{P}_{th}(\tilde{V})}{\tilde{T}} + \frac{\tilde{P}_i(\tilde{V})}{\tilde{T}} \qquad \text{(A9)}$$

where the dimensionless variables are defined as before Eq. (A7). The physical meaning of the characteristic parameters P^*, V^*, T^* vary among the models. But in general, V^* is related to the van der Waals volume, T^* is proportional to monomer–monomer interaction energy, and P^* is related to the cohesive energy density.

Simple Cell Model of Prigogine et al. The cell model by Prigogine et al. (10–12) is an extension of the cell model for small molecules by Lennard–Jones and Devonshire (68) to polymers. Each monomer in the system is considered to be trapped in the cell created by the surroundings. The general cell potential, generated by the surroundings, is simplified to be athermal. This turns the simple cell model into a free volume theory. The mean potential between the centers of different cells are described by the Lennard–Jones 6–12 potential. The dimensionless equation of state has the following form:

$$\frac{\tilde{P}}{\tilde{T}} = \frac{1}{\tilde{V}^{2/3}(\tilde{V}^{1/3} - 2^{-1/6})} - \frac{2}{\tilde{T}}\left(\frac{1.2045}{\tilde{V}^3} - \frac{1.011}{\tilde{V}^5}\right) \quad \text{(A10)}$$

The factor $2^{-1/6}$ originates in the choice of the hexagonal close packing lattice as a cell geometry. The factors 1.2045 and 1.011 correct the effects of higher coordination shells on the internal energy.

Table 6 gives the three characteristic parameters P^*, V^*, T^* for the Prigogine cell model for the polymers in Tables 1 and 2. The average deviation between Eq. (A10) and regenerated *PVT* data is 0.0008 cm^3/g.

Cell Model by Flory, Orwoll, and Vrij (FOV) The cell model by Flory et al. (14) has the simpler mathematical form than the Prigogine cell model:

$$\frac{\tilde{P}}{\tilde{T}} = \frac{1}{\tilde{V}^{2/3}(\tilde{V}^{1/3} - 1)} - \frac{1}{\tilde{T}\tilde{V}^2} \quad \text{(A11)}$$

The Lennard–Jones energy is replaced with a uniform background (van der Waals) energy.

The characteristic parameters P^*, V^*, T^* for the FOV theory are shown in Table 7. The average deviation between Eq. (A11) and regenerated *PVT* data is 0.0022 cm^3/g. It has often been pointed out that the fitting performance of the FOV theory is less accurate, especially when covering a large pressure range. However, we present the parameters for the whole pressure range. This will provide a guidance when one fits the *PVT* data for smaller pressure ranges of interest.

Hole Model by Simha and Somcynsky (S–S) The simple cell model by Prigogine et al. is modified by Simha and Somcynsky (13) to allow for lattice imperfections (holes). The model can be written as the following equation of state:

$$\frac{\tilde{P}}{\tilde{T}} = \frac{(y\tilde{V})^{1/3}}{\tilde{V}[(y\tilde{V})^{1/3} - 2^{-1/6}y]} - \frac{2y}{\tilde{T}\tilde{V}}\left(\frac{1.2045}{(y\tilde{V})^2} - \frac{1.011}{(y\tilde{V})^4}\right) \quad \text{(A12)}$$

where the factor "y" is the fraction of occupied lattice sites and satisfies

$$(s/3c)[1 + \ln(1-y)/y] = -\frac{[(y\tilde{V}^{1/3}/3 - 2^{-1/6}y]}{[(y\tilde{V})^{1/3} - 2^{-1/6}y]} - \frac{y}{6\tilde{T}}\left(\frac{2.409}{(y\tilde{V})^2} - \frac{3.033}{(y\tilde{V})^4}\right) \quad \text{(A13)}$$

The factor $s/3c$ in Eq. (A13) is called the flexibility ratio, which is usually set to 1. Other factors are the same as those in the Prigogine cell model.

In order to calculate volume at given temperatures and pressures, one should solve Eqs. (A12) and (A13) simultaneously. The calculational complexity is a drawback of this model. Simha and Somcynsky suggested the approximate representation of the S–S equation of state:

$$\tilde{V} = 0.9018\exp(23.835\tilde{T}^{3/2}) [1 - 0.089\ln\{1 + 1.0472\tilde{P}\exp(49.22\tilde{T})\}] \quad \text{(A14)}$$

The characteristic parameters P^*, V^*, T^* for the S–S theory are shown in Table 8. The parameters are obtained by fitting the original S–S equation of state in Eq. (A12) with Eq. (A13), rather than fitting Eq. (A14). The average deviation between Eq. (A12) and regenerated *PVT* data is 0.0007 cm^3/g.

Lattice Fluid Model The Lattice Fluid model developed by Sanchez and Lacombe (15,16) introduces vacancies into the classical incompressible Flory–Huggins model. The lattice vacancy is treated as a pseudo particle in the system. The free energy of an incompressible binary polymer solution is then converted to that of the bulk polymer. The equation of state for a polymer is given below:

$$\frac{\tilde{P}}{\tilde{T}} = -\left[\ln\left(1 - \frac{1}{\tilde{V}}\right) + \frac{1}{\tilde{V}}\right] - \frac{1}{\tilde{T}\tilde{V}^2} \quad \text{(A15)}$$

Table 9 gives the three characteristic parameters P^*, V^*, T^* for the lattice fluid (LF) theory. As was with the FOV model, the LF model does not correlate *PVT* data well over large pressure ranges. The average deviation between Eq. (A15) and regenerated bulk *PVT* data is 0.0033 cm^3/g.

E. CONTINUUM MODELS

The widely used models presented in the last section are derived by considering the partition function of a chain system on a lattice or quasi lattice. The lattice or quasi lattice phase space can be further generalized to be a continuum counterpart. This approach yields, in general, the integral equation theory, which focuses on solving the integral equations of the particle-particle distribution functions (9). The system of hard chains has been treated the most, because it is the simplest and provides the possibility of analytical equation of state in some cases.

One approach of this category is to solve the integral equations using the Percus–Yevick closure for the system of adhesive hard sphere (AHS) mixtures (17–22). An adhesive hard sphere is a hard sphere that has attractive sites at surface. The attractive interaction on these attractive sites is infinitely strong and infinitesimally short ranged. The Percus–Yevick closure yields an analytical solution for such systems. The adhesive attraction, which resembles the chemical bonding, is used to build up chains by employing the proper connectivity constraints.

A different approach of this category is to manipulate the graphs in the cluster expansion of the system of hard spheres with multiple attractive sites (23–29). The attractive interaction is the same as that of the AHS system, and is treated as a perturbation to the reference hard

sphere potential. The steric incompatibility is taken into account by Wertheim to approximate the graph expansion for distribution functions. This approach is called the thermodynamic perturbation theory (TPT) (23–27) or the statistically associating fluid theory (SAFT) (28,29).

A unique approach to the hard chain equation of state has been developed by Hall and coworkers (30). Flory's on-lattice particle insertion analysis is generalized to the off-lattice calculation. This theory is called the generalized Flory (GF) model. The enhanced evaluation of the insertion probability is further manipulated to yield the equation of state.

Since the developed equations of state are for athermal chain systems, an energetic contribution to pressure is required in order for these models to be applicable to real systems. The simplest model adds a van der Waals (vdW) term as a perturbation to the reference pressure (28,31):

$$\frac{\tilde{P}}{\tilde{T}} = \left(\frac{\tilde{P}}{\tilde{T}}\right)_0 - \frac{1}{\tilde{T}\tilde{V}^2} \qquad \text{(A16)}$$

where the term with the subscript 0 implies the athermal reference pressure. The dimensionless variables are defined as usual (Eq. (A7)).

The specific mathematical forms of the reference equation of state are as follows:

$$\left(\frac{\tilde{P}}{\tilde{T}}\right)_0 = \frac{3}{2}\frac{1+1/\tilde{V}}{\tilde{V}^2(1-1/\tilde{V})^3} \quad \text{(AHS)} \qquad \text{(A17)}$$

$$\left(\frac{\tilde{P}}{\tilde{T}}\right)_0 = \frac{3}{\tilde{V}^2(1-1/\tilde{V})^3}\left[1-\frac{(1-1/\tilde{V}^2)}{(2+1/\tilde{V})}\right] \quad \text{(TPT or SAFT)} \qquad \text{(A18)}$$

$$\left(\frac{\tilde{P}}{\tilde{T}}\right)_0 = 1.31659\frac{2-1/\tilde{V}}{\tilde{V}^2(1-1/\tilde{V})^3} \quad \text{(GF)} \qquad \text{(A19)}$$

The three characteristic parameters P^*, V^*, T^* for the AHS + vdW equation of state are shown in Table 10. The average deviation between the AHS + vdW equation and regenerated bulk data is 0.0012 cm^3/g. The parameters for other two equations are relatively close to those for the AHS + vdW equation, and are not tabulated here.

A. INTRODUCTION

1. The Viscosity – Molecular Weight Relationship

The limiting viscosity number $[\eta]$ of a solution – which has long been called the intrinsic viscosity – is defined as

$$[\eta] = \lim_{c \to 0} \frac{\eta - \eta_0}{\eta_0 c} \qquad \text{(A1)}$$

in terms of the solvent viscosity, η_0, the solution viscosity, η, and the solute concentration, c. The concentration, c, is expressed in grams of solute per milliliter of solution or, more frequently, in grams of solute per 100 milliliters of solution, the limiting viscosity number being given in the reciprocal of these units, *i.e.*, in milliliters per gram or in deciliters per gram. Here, following the IUPAC 1952-recommendations (1), we adopt the former unit. The quantity $[\eta]$ of a polymer solution is a measure of the capacity of a polymer molecule to enhance the viscosity, which depends on the size and the shape of the polymer molecule. Within a given series of polymer homologs, $[\eta]$ increases with the molecular weight M; hence it is a measure of M.

Section C gives the limiting viscosity number – molecular weight relationships for polymers, in various solvents and at various temperatures. The table contains the constants of the equation

$$[\eta] = KM^a \qquad \text{(A2)}$$

which is known as the Mark–Houwink–Sakurada equation. It is now well established that for linear, flexible polymers, under special conditions of temperature or solvent, (usually known as the Flory "theta" temperature or solvent, (2)), the above equation becomes

$$[\eta]_\theta = K_\theta M^{0.50} \qquad \text{(A3)}$$

In the tables, the θ sign in parenthesis (next to the temperature data) indicates that the viscosity constants were obtained under the theta condition. Since Eq. (A3) is approximately valid over the whole molecular weight range, K_θ and $a = 0.50$ may be used without modification, outside of the molecular weight range in which they were determined. However, it must be noted that $[\eta]$ is rather sensitive to temperature in the vicinity of θ, especially when M is higher than 5×10^5.

In ordinary good solvents, the constants K and a obtained are valid only within a rather limited range of M (3,4). It is therefore, quite probable that the tabulated relationships are in error outside the indicated range of M (see eighth column in the table). As for the effect of temperature, however, both K and a mostly become insensitive to the temperature when a exceeds about 0.70, and they may be used in a 10-degree range on either side of temperature at which the constants were determined.

The method of determination of the molecular weight and the number of fractionated samples (Fr.) or whole polymer samples (WP) used to determine the $[\eta]$–M relationship are also given in the ninth and the sixth or seventh columns, respectively. The abbreviations used are as follows:

(A) Methods Yielding the Number-Average Molecular Weight (M_n)

CR	cryoscopy
EG	end-group titration
VOS	vapor pressure osmometry
EB	ebullioscopy
OS	osmotic pressure

(B) Methods Yielding the Weight-Average Molecular Weight (M_w)

LS	light scattering
LLS	low-angle laser light scattering
SE	sedimentation equilibrium
SEC, GPC	size exclusion chromatography gel permeation chromatography
SA	approach to the sedimentation equilibrium (Archibald's method)

(C) Empirical or Semi-Empirical Methods

EM	electron microscopy
GPC	gel permeation chromatography
LV	limiting viscosity number – molecular weight relationship
PR	analysis of polymerization rate (yielding M_n)
DV	diffusion and viscosity
MV	melt viscosity – molecular weight relationship
SD	sedimentation and diffusion
SV	sedimentation and viscosity

Thus, for example, the constants tabulated are for the $[\eta]$–M relationships, expressed in terms of M_n or M_w, if the method is specified as OS or LS, respectively; *i.e.*,

$$[\eta] = K_n M_n^a \qquad \text{(A4)}$$

or

$$[\eta] = K_w M_w^a \qquad \text{(A5)}$$

The values of K_n and K_w, especially the former, are greatly influenced by the molecular weight distribution (MWD) of the polymer samples, and caution must be taken in using these relationships.

To illustrate this effect, let us assume that

(i) Equation (A2) is applicable to the molecule i with molecular weight M_i over the whole range of M; *i.e.*,

$$[\eta]_i = KM_i^a \qquad \text{(A6)}$$

(ii) The weight fraction w_i of the molecules i in a given sample can be represented by a continuous exponential function,

$$w_i(M_i) = [y^{h+1}/\Gamma(h+1)]\, M_i^h \exp(-yM_i) \qquad \text{(A7)}$$

$$y = h/M_n = (h+1)/M_w \qquad \text{(A8)}$$

or by the log-normal function,

$$w_i(M_i) = AM_i \exp[-p^2(\ln M_i/M_0)^2] \qquad \text{(A9)}$$

where h, A, p, and M_0 are constants, and Γ represents the gamma function.
Then, since $[\eta] = \sum_i w_i[\eta]_i$, we obtain

$$K_n = K\Gamma(a+h+1)/h^a\Gamma(h+1) \qquad \text{(A10)}$$

$$K_w = K\Gamma(a+h+1)/(h+1)^a\Gamma(h+1) \qquad \text{(A11)}$$

for the exponential MWD, and

$$K_n = K(M_w/M_n)^{0.5a(a+1)} \qquad \text{(A12)}$$

$$K_w = K(M_w/M_n)^{0.5a(a-1)} \qquad \text{(A13)}$$

for the log-normal MWD (5). The values of K_n/K and K_w/K calculated by these equations are shown in Section B. This table may be used for estimating an error due to MWD in the determination of M.

As an example, let us assume that a given polymer sample has the exponential MWD with $M_w/M_n = 2.0$, while an available $[\eta]-M_n$ equation has been obtained for samples with a narrow MWD, *e.g.*, $M_w/M_n = 1.1$. Further, let a be 0.70. Then, to find the correct value of M_n of the given sample from $[\eta]$, we must use Eq. (A4) with $K_n = 1.54K$, instead of the available equation with $K_n = 1.06K$. Use of the latter would lead to an overestimate M_n' which is related to the correct M_n by

$$[\eta] = 1.54KM_n^{0.70} = 1.06KM_n'^{0.70} \qquad \text{(A14)}$$

The error amounts to about 70%, *i.e.*, $M_n' = 1.7M_n$. Thus, application of the viscosity equation written in M_n is to be restricted to within a narrow class of samples, unless an appropriate correction is made. On the other hand, if an $[\eta]-M_w$ equation is available for the same pair of working and reference samples as above, we have

$$[\eta] = 0.951KM_w^{0.70} = 0.991KM_w'^{0.70} \qquad \text{(A15)}$$

instead of Eq. (A14). Hence, the error M_w amounts to only 6% ($M_w' = 0.94M_w$), which will be negligible for more practical purposes.

Based on the above consideration, we classify the heterogeneity of polymers into four classes, A–D, as shown in the last column of the table in Section B, and indicate it in the tenth column of the tables in Section C, as a measure of the heterogeneity of the reference samples used.

It is desirable that readers select their own relationship by inspecting these data on heterogeneity as well as those on the number of samples and the molecular weight range. Generally speaking, a "good" $[\eta]-M$ relationship is one that has been obtained on the basis of M_w for at least four samples of classes A and B (exceptionally C) or on the basis of M_n for those of class A (exceptionally B), whose molecular weights range over at least one half orders of magnitude.

In the "Remarks" column of Section C, we have occasionally indicated by the letter R, a "recommended" relationship for the convenience of readers. In the range of low molecular weight (mostly less than 10^4), the constant a becomes 0.50 irrespective of the solvent. This type of relationship cannot be used, even approximately, at higher molecular weights. This case is noted by the letter L. High conversion polymers are also marked by the letter H, where the $[\eta]-M$ relationships are less reproducible due to chain branching than are ordinary ones. The abbreviations used are as follows:

A	Narrow MWD polymers, or well-fractionated polymers, $M_w/M_n \leq 1.25$
B	Ordinary fractionated polymers, $1.30 \leq M_w/M_n \leq 1.75$
C	Poorly fractionated polymers or most probable MWD polymers, $1.8 \leq M_w/M_n \leq 2.4$
D	Wide MWD polymers, $M_w/M_n \geq 2.5$
H	High conversion polymers, including branches
L	Limited to low-molecular-weight polymers
R	Recommended relationship

In Section C, polymers are arranged according to their structure in subgroups. Within each subgroup, the polymers are, in principle, given in alphabetical order. Within each polymer, the solvents are also arranged in alphabetical order, followed by the mixed solvents.

Chain configurational data are occasionally given in the first column. The data given in parentheses refer to only one set of viscosity constants listed in the same row, while the data given without parentheses refer to a series of sets listed in the same and succeeding rows. Thus, for example, the data "N content, 13.9 wt.%" are effective only for the sixth row of cellulose trinitrate, and the data "95%-*cis*, 1%-*trans*, 4%-1,2" are effective for the fourth to eighth rows of polybutadiene.

The tables in Section C are essentially based on the table published by Kurata and Stockmeyer (3). Data were also taken from tables published by Peterlin (7), Meyerhoff (8), Elias (9), and Krause (10), the last one including a number of unpublished data on acrylic and methacrylic polymers. We are also grateful to these authors. Thanks are also due to J. Brandrup and K. Kamide for their help with this compilation.

References page VII - 68

2. Unperturbed Dimensions of Linear Chain Molecules

The mean-square end-to-end distance $\langle r^2 \rangle$ of a linear chain molecule in solution is usually expressed in terms of two basic quantities, the unperturbed mean-square end-to-end distance $\langle r^2 \rangle_0$ and the expansion factor α; *i.e.*,

$$\langle r^2 \rangle = \langle r^2 \rangle_0 \alpha^2 \qquad \text{(A16)}$$

The latter quantity α represents the effect of "long-range interactions" which can be described as an osmotic swelling of the chain by the solvent–polymer interactions, while the unperturbed dimension $\langle r^2 \rangle_0$ represents the effect of "short-range interactions" such as bond angle restrictions and steric hindrances to internal rotation. The steric hindrances are also influenced by the torques exerted on the chain by solvent molecules, but the effect is rather small in many cases (11).

For sufficiently long chain, $\langle r^2 \rangle_0$ becomes proportional to $\sum_i n_i l_i^2$ where n_i is the number of the ith-kind bond of length l_i. The quantity C_∞, defined by

$$C_\infty = \lim_{n \to \infty} \langle r^2 \rangle_0 \Big/ \sum_i n_i l_i^2 \qquad \text{(A17)}$$

is often called the characteristic ratio and it serves as a measure of the effect of short-range interactions.

The freely rotating state is a hypothetical state of the chain in which the bond angle restrictions are retained, but the steric hindrances to internal rotation are released. The mean-square end-to-end distance of the freely rotating chain $\langle r^2 \rangle_{0f}$ can be readily calculated from the given basic structure of the chain. For instance, if the chain consists of only one kind of bond of length l, we obtain

$$\langle r^2 \rangle_{0f} = nl^2[(1 + \cos\theta)/(1 - \cos\theta)] \qquad \text{(A18)}$$

where n is the number of bonds and θ is the supplement of the valence bond angle. For vinyl polymer chains, $l = 0.154$ [nm], $\cos\theta = 1/3$, and $n = M/m = 2M/M_u$; and hence

$$(\langle r^2 \rangle_{0f}/M)^{1/2} = 0.308/M_u^{1/2} = 0.218/m^{1/2}\,[\text{nm}] \qquad \text{(A19)}$$

where M_u is the molecular weight of the repeating unit and m is the average molecular weight per skeletal link. Similar expressions for r_{0f} $(= \langle r^2 \rangle_{0f}^{1/2})$ can be also obtained for more complicated chains. The results are summarized in Section D.

The ratio of $\langle r^2 \rangle_0$ to $\langle r^2 \rangle_{0f}$, then, represents the effect of steric hindrance on the average chain dimensions:

$$\sigma = r_0/r_{0f} = (\langle r^2 \rangle_0 / \langle r^2 \rangle_{0f})^{1/2} \qquad \text{(A20)}$$

The quantity σ is independent of n. Section E gives a list of the unperturbed dimensions of linear chain molecules which were obtained under various conditions of solvent and temperature. The values of $r_0/M^{1/2}$, $r_{0f}/M^{1/2}$, σ and C_∞ are given, together with the experimental values of $S_{0z}/M_w^{1/2}$, a_p, or K_0 from which r_0 was computed. S_{0z} which is the abbreviation of $\langle S^2 \rangle_{0z}^{1/2}$ is the z-average value of the unperturbed radius of gyration, a_p is the persistence length, and K_0 is the viscosity constant corresponding to K_θ in Eq. (A3). The methods used to determine these quantities are also indicated in the tenth column of the tables by using the following abbreviations:

(A) Light scattering

- LT Zimm's plot in a theta solvent yielding $S_{0z}/M_w^{1/2}$. After a heterogeneity correction is made, the tabulated value of $r_0/M^{1/2}$ $(= 6^{1/2} S_{0w}/M_w^{1/2})$ is obtained.
- LD dissymmetry method in a theta solvent. Less reliable for heterogeneous samples than the former method.
- LG Zimm's plot in good solvents yielding $S_z/M_w^{1/2}$. After corrections for the excluded volume effect and heterogeneity are made, the tabulated value of $r_0/M^{1/2}$ is obtained (3,12).

(B) X-ray small-angle scattering

- XS the persistence length a_p is obtained irrespective of the solvent nature. The tabulated values of $r_0/M^{1/2}$ are the asymptotic values for infinitely high molecular weight (13,14).

(C) Limiting viscosity number

- VT viscosity – molecular weight relationship in a theta solvent. Equation (A3) $r_0/M^{1/2}$ is calculated by the Flory and Fox relation, $K_0 = \Phi_0 (r_0/M^{1/2})^3$. The following values of Φ_0 were used:
  - 2.7×10^{23} for well-fractionated polymers (class A in Section C)
  - 2.5×10^{23} for ordinary fractionated polymers (class B)
  - 2.1×10^{23} for poorly fractionated or unfractionated polymers (class C or D)
- VG viscosity – molecular weight relationship in good solvents. K_0 was estimated by using the Kurata–Stockmeyer–Fixman plot (3,4) or other analogous plots (12).
- VWC viscosity analyzed by the wormlike cylinder model.
- VA viscosity in good solvents. The correction of excluded volume effect is made by using the Flory–Krigbaum–Orofino theory of the second virial coefficient A_2 or other analogous theories (12).

(D) Method yielding the temperature dependence of r_0.
- ST stress – temperature coefficient of undiluted or swollen samples.
- VTe viscosity – temperature coefficient of the intrinsic viscosity

The polymers are arranged in Section E in the same order as in Section C. For each polymer, smoothed values of $r_0/M^{1/2}$, σ, and C_∞, which were mostly obtained by VT or VG, are given in the first line, followed by some typical values obtained by more direct methods such as LT or XS. The listed values of $r_0/M^{1/2}$ sometimes scatter appreciably, reflecting the difficulty involved, both experimental and theoretical, in the determination of this quantity. Especially in the case of cellulose chains, the right magnitude of r_0 is yet in controversy (542, 549,3,691,696,688,678,686,12). In recent papers, emphasis has often been put on the effect of temperature or solvent on the unperturbed dimensions. These data are put together at the end of the tabulation for each polymer. Section E is also based on the tables published by Kurata and Stockmeyer (3).

* These values of r_{0f} of poly(epoxide) chains were calculated by $0.377/M_u^{1/2}$ [nm.mol$^{1/2}$/gram$^{1/2}$], while those given without asterisk were calculated by $0.360/M_u^{1/2}$. The former is due to Allen et al. (Ref. 695). The latter is based on the assumption that all valence angles of skeleton are tetrahedral.

A. SEDIMENTATION COEFFICIENTS, DIFFUSION COEFFICIENTS, PARTIAL SPECIFIC VOLUMES, AND FRICTIONAL RATIOS OF POLYMERS IN SOLUTION

(2, 349–357, 799, 800)

1. Introduction

1.1. Sedimentation Coefficient The sedimentation coefficient s is defined as the sedimentation velocity in a unit force field

$$s = (\mathrm{d}r/\mathrm{d}t)/(\omega^2 r) \tag{A1}$$

where r is the distance from center of rotation, and ω, the angular velocity. For a given polymer–solvent system, the sedimentation coefficient is dependent on temperature T, pressure p, and polymer concentration C. Experimentally, sedimentation coefficients can be determined only with an ultracentrifuge.

Concentration Dependence
For polymer solutions studied by ultracentrifugation, the following concentration dependence of the sedimentation coefficient holds:

$$1/s = (1/s_0)(1 + k_s C + k_s' C^2 + \cdots) \tag{A2}$$

where s_0 is the sedimentation coefficient at zero concentration. In Section B the concentration dependence of s according to Eq. (A2) is listed. In some cases, special extrapolation procedures are used. The tables in Section B also refer to the appropriate reference. For special treatments, see, e.g., Gehatia (358,359).

Sector shaped cells are normally used in an ultracentrifuge. In these cells, the square-dilution rule has to be taken into account (360):

$$C_t/C_0 = (r_0/r_t)^2 \tag{A3}$$

where r_0 and r_t are the distances of the meniscus and of the boundary from the axis of rotation and C_0 and C_t the concentrations at zero time and at time t at the boundary, respectively.

Averages of the Sedimentation Coefficient
The average of a function $X(M)$ is defined as

$$X_\beta = \left(\int_0^\infty W(M)M^{\beta-1}X(M)\,\mathrm{d}M\right) \Big/ \left(\int_0^\infty W(M)M^{\beta-1}\,\mathrm{d}M\right) \tag{A4}$$

with $\int_0^\infty W(M)\,\mathrm{d}M = 1$, where $W(M)$ denotes the probability density function (in our case the molar mass distribution). The average with $\beta = 0$ is called the number average X_n, with $\beta = 1$, the mass average X_w, and with $\beta = 2$, the z-average X_z.

In principle it is possible to evaluate the various averages of the sedimentation coefficient from the distribution of the concentration gradient, $\partial C/\partial r$, in the cell:

$$s_\mathrm{n} = M_\mathrm{n} \int_0^\infty W(M)M^{-1}s(M)\,\mathrm{d}M$$
$$s_\mathrm{w} = \int_0^\infty W(M)s(M)\,\mathrm{d}M$$
$$s_\mathrm{z} = (1/M_\mathrm{w}) \int_0^\infty W(M)Ms(M)\,\mathrm{d}M \tag{A5}$$

where $W(M) = C(M)/\int_0^\infty C(M)\,\mathrm{d}M = C(M)/C_0$ is the mass distribution of the polydisperse polymer in the cell and s_n, s_w, and s_z the number average, mass average and z-average of the sedimentation coefficient. In many cases the migration of the maximum of the quantity $\partial C/\partial r$ is determined, which leads to a sedimentation coefficient s_t, that in turn is related, in a complicated manner, to the averages of s in Eq. (A5). Another method of evaluating the sedimentation coefficient is by observing the median, that is the line dividing the gradient curve in two equal areas, yielding a value s_m which is also a rather complicated average. Provided the skewness of the molar mass distribution is not very pronounced, s_w can be calculated by (Ref. 259)

$$s_\mathrm{w} = (3s_\mathrm{m} - s_t)/2 \tag{A6}$$

Most ultracentrifuges measure the refractive index difference between polymer and solvent, dn, or the refractive index gradient $\partial n/\partial r$ versus r (Schlieren optics). With certain assumptions $\partial n/\partial r$ can be related to the concentration gradient (Ref. 14)

$$\partial n/\partial r = R(\partial C/\partial r) \tag{A7}$$

where R is called the specific refractive index increment. The interference optics measure the deflection of the parallel interference lines in the solution. This deflection is directly proportional to the concentration of the polymer.

The absorption optics measure the optical density of the system as a function of the rotor distance, which, according to the Lambert–Beers law is proportional to the concentration of the polymer. The intensity is measured with a photoelectric scanner.

A multiplexer is used in order to measure several concentrations during one run (869–871).

Sedimentation Coefficient – Molar Mass Relationship
The dependence of s on the molar mass can be given by a power law expression:

$$s = K_s M^{a_s} \tag{A8}$$

where K_s and a_s are empirical constants determined for each polymer–solvent system at given values of temperature and pressure. In Section B, relationship (A8) is listed whenever quoted in the literature, in preference to single s values,

Temperature Dependence, Pressure Dependence
Svedberg and Pedersen (2) and Mosimann and Signer (361) derived expressions for the temperature and pressure dependence of the sedimentation coefficient with restricted validity:

$$s/s^\theta = (\eta_1^\theta/\eta_1)(1 - v_2^\theta \rho_1^\theta)/(1 - v_2\rho_1) \tag{A9}$$

where s^θ, η_1^θ, v_2^θ and ρ_1^θ denotes the values at the reference temperature and/or pressure. Equation (A9) holds in the case of an incompressible medium and if no changes of size, shape and solvation state of the dissolved molecules in the temperature and pressure region take place. From these assumptions it may be deduced that Eq. (A9) can be applied with sufficient accuracy only on proteins in aqueous solvents.

Due to the high centrifugal fields applied in the ultracentrifuge, pressure gradients with pressures up to 200 bars are encountered in the cell and change appreciably the viscosity and the density of the solvent and the partial specific volume of the polymer. Thus the sedimentation coefficient, s, measured at a pressure p differs from the sedimentation coefficient, s^0, measured at 0 bar. Application of Eq. (A9) for the calculation of s requires the knowledge of η_1 (362), ρ_1 (given in a number of Handbooks) and v_2 (148). More precise equations for the calculation of the pressure influence on the sedimentation have been worked out by several authors (363,364,365,800). The equation of Oth and Desreux (Ref. 363)

$$s = s^0(1 - \mu p) \tag{A10}$$

has very often been used for the calculation of s^0 (800). The coefficient μ depends on the polymer–solvent system and varies only slightly with pressure.

In Section B, the intrinsic sedimentation coefficient, $[s^0]$, instead of s^0, has been occasionally listed. $[s^0]$ is related to Eq. (9): $[s_0] = s_0\eta_1/(1 - v_2\rho_1)$.

1.2. Diffusion Coefficient

The translational diffusion coefficient D is defined by Ficks' first law:

$$J = -D\nabla C \tag{A11}$$

where J is the flow of substance (total number of particles transported in unit time across unit surface) and ∇C the concentration gradient. For one dimensional diffusion, Eq. (A11) reduces to

$$(1/A)(\partial n/\partial t) = -D(\partial C/\partial r) \tag{A12}$$

where A denotes the area and n the number of moles. The negative sign in Eqs. (A11) and (A12) indicate that diffusion takes place in the direction of decreasing concentration. For practical reasons, Ficks second law is prefered

$$(\partial C/\partial t) = D\Delta C \tag{A13}$$

where Δ denotes the Laplace operator. Eq. (A13) reduces to

$$(\partial C/\partial t) = D(\partial^2 C/\partial r^2) \tag{A14}$$

for the one dimensional case. Eqs. (A13) and (A14) allow the determination of D when solved with consideration to certain initial and boundary conditions.

Experimentally translational diffusion coefficients can be determined with an ultracentrifuge (see Section 1.3) in special diffusion cells using Eqs. (A11)–(A14) (800) and with dynamic light scattering (DLS). Since 1970, when the dynamic light scattering became available, nearly all diffusion coefficients have been measured by this method. Based on the theory of Pecora (853,854), the experimentally measured autocorrelation function $g_2(t)$ is linked with the diffusion coefficient in polymer solutions (Refs. 730,855):

$$\lim_{c\to 0} g_2(t) = A + B\left(M_w^{-1}\int_0^\infty MW(M)p(q,M)\exp(-q^2D(M)t)\mathrm{d}M\right)^n \tag{A15}$$

where $n = 1$ for the heterodyne procedure and $n = 2$ for the homodyne one. Eq. (A15) reduces, in the case of a monodisperse polymer solution, to

$$\lim_{c\to 0} g_2(t) = A + B(p(q,M)\exp(-q^2D(M)t))^n \tag{A16}$$

References page VII - 198

A and B are measurable constants. Extrapolation of q against zero yields $P(q, M) = 1$. Note that $g_2(t)$ is the z-average of the function, $\exp(-q_2 D(M)t)$. In this way one obtains the direct measurable quantity D_z from dynamic light scattering on polydisperse polymer solutions.

For polydisperse polymer solutions, Eq. (A16) may be expanded in a series (Ref. 856):

$$\lim_{\substack{C\to 0\\ q\to 0}} g(t) = \exp(-q^2 D_z t)\,(1 + (\mu_2/2!)t^2 - (\mu_3/3!)t^3 + \cdots) \tag{A17}$$

where the moments, μ_i, are related to the molar mass distribution of the polymer (671).

More general methods for the determination of the distribution of the diffusion coefficient and of the molar mass are given elsewhere (857,858).

As has been pointed out, only the translational diffusion coefficient is listed in the tables. For higher modes of the autocorrelation function (e.g. rotation, vibration) see the appropriate literature (853,854).

The entire description of the translational diffusion of a polymer molecule in solution requires the determination of the mutual or cooperative diffusion coefficient, D_m, which characterizes the relaxation of a concentration gradient and the self-diffusion coefficient, D_s, which describes the Brownian or random motions of the polymer molecule (860–863).

$$D_m = (RT/f)\,(1 - v_2\rho_1)\,(1 + 2A_2MC + 3A_3MC^2 + \cdots)$$
$$D_s = RT/f$$

At infinite dilution, $D_m = D_s \times D_m$ is normally measured with classical diffusion cells or dynamic light scattering whereas D_s can be studied by measuring the migration of labeled solute molecules (864), by pulsed field gradient NMR (865), and by forced Rayleigh scattering (866). Normally, D_m is given in the tables. In some cases, especially where D_s is extrapolated to zero concentration, $D_s = D_m$ is given in the tables.

Concentration Dependence

The concentration dependence of the diffusion coefficient may be described as

$$D = D_0(1 + k_D C + k'_D C^2 + \cdots) \tag{A18}$$

where D_0 is the diffusion coefficient at zero concentration. In Section B a concentration dependence of D according to Eq. (A18) is listed. In some cases, special extrapolation procedures are used. In these cases Section B refers to the appropriate references.

Averages of the Diffusion Coefficient

Similar considerations as made on sedimentation coefficients hold for diffusion coefficients. From measurements in a diffusion cell, one obtains the various averages of the diffusion coefficient from the distribution of the concentration gradient, $\partial C/\partial r$, in the cell:

$$D_n = M_n \int_0^\infty W(M)M^{-1}D(M)\,dM$$
$$D_w = \int_0^\infty W(M)D(M)\,dM$$
$$D_z = (1/M_w)\int_0^\infty W(M)MD(M)\,dM \tag{A19}$$

where $W(M) = C(M)/C_0$.

The diffusion cell may be combined in the same manner as in the case of the ultracentrifuge with Schlieren optics, interference optics, and absorbtion optics. In most cases, the mass average and the area average of the diffusion coefficient are determined. They can be calculated with the help of Eqs. (A14) and (A19):

$$D_w = \left(\int_0^\infty r^2(\partial C/\partial r)\,dr\right) \Bigg/ \left(2t\int_0^\infty (\partial C/\partial r)\,dr\right) \tag{A20}$$

$$D_A = \int_0^\infty ((\partial C/\partial r)\,dr)^2/(4\pi t(\partial C/\partial r)_{max})^2 \tag{A21}$$

$(\partial C/\partial r)_{max}$ is the maximum height of $\partial C/\partial r$. The integral in Eq. (A21) is the area of the curve.

As has been pointed out, dynamic light scattering measurements normally yield the z-average of D. Nevertheless it might be possible to determine averages other than D_z with the help of Eqs. (A19) and (A21). In Section B the different averages of D are quoted. In some cases unusual averages are listed. In these cases Section B refers to the appropriate references.

Diffusion Coefficient – Molar Mass Relationship

The diffusion coefficient – molar mass dependence frequently takes the form

$$D = K_D M^{-a_D} \tag{A22}$$

where K_D and a_D are constants for each polymer–solvent system at given values of temperature and pressure. In Section B relationship A(22) is listed whenever quoted in the literature, in preference to single D values.

Temperature Dependence, Pressure Dependence

A similar expression as Eq. (A9) holds under the same restricted conditions for the temperature and pressure dependence of the diffusion coefficient:

$$(D/T)/(D^\theta/T_0) = \eta_1^\theta/\eta_1 \tag{A23}$$

where D^{θ} and η_1^{θ} denote the values at the reference temperature T_0 and/or pressure p_0. As has been pointed out in Eq. (A9), Eq. (A23) can be applied with sufficient accuracy on proteins in aqueous solvents only.

The temperature dependence of the diffusion coefficient is often described by the following exponential function

$$D = D_{\infty} \exp(-E_D/RT) \qquad \text{(A24)}$$

where E_D denotes the apparent activation energy of the diffusion and D_{∞} the diffusion coefficient at the limit $T = \infty$. In Section B we have listed the temperature and pressure dependence of D whenever quoted in the literature.

1.3. Molar Mass Averages Determined from Sedimentation and Diffusion Coefficients For the experimental determination of the molar mass from sedimentation and diffusion measurements, the Svedberg Eq. (A2) is used:

$$M = (s_0/(1/v_2\rho_1))/(D_0/RT) \qquad \text{(A25)}$$

Here s_0 and D_0 are the corrected and standardized coefficients for zero polymer concentration. For polydisperse polymers the various averages of the sedimentation and diffusion coefficient s and D are inserted, obtaining certain molar mass averages $M_{\beta,\gamma}$. Thus Eq. (A25) acquires the more general form:

$$M_{\beta,\gamma} = (s_{0,\beta}/(1 - v_2\rho_1))/(D_{0,\gamma}/RT) \qquad \text{(A26)}$$

For β = n, w, z, ... and γ = n, w, z, ... Eq. (A26) defines several different molar mass averages $M_{\mathrm{n,n}}$, $M_{\mathrm{w,n}}$, $M_{\mathrm{w,w}}$ etc. The averages, $M_{\mathrm{n,n}}$, and $M_{\mathrm{w,w}}$, are different from M_{n} and M_{w} respectively (859). The coefficients with β = n and z and γ = n are determinable only with large error. Instead, the coefficients with $\beta = t$ and m (see under Section 1.1.) and γ = A and w (see under Section 1.2.) are usually evaluated. Thus, rather peculiar averages, e.g. $M_{t,\mathrm{A}}$, $M_{\mathrm{m,w}}$, and $M_{\mathrm{m,A}}$, result. The more straightforward molar mass averages $M_{\mathrm{n,w}}$, $M_{\mathrm{w,w}}$, $M_{\mathrm{z,w}}$, etc., in relation to the familiar averages, M_{n}, M_{w}, and M_{z}, are found elsewhere in the literature (369–371,859).

1.4. Partial Specific Volumes The volume, V^{id}, of an ideal two component system can be expressed in terms of the masses m_1 and m_2 and the specific volumes, v_1^0 and v_2^0, of the two components by the equation

$$V^{\mathrm{id}} = m_1 v_1^0 + m_2 v_2^0 \qquad \text{(A27)}$$

Most components do not behave ideally upon mixing; i.e. they react with each other in a way so that the total volume deviates from V^{id}. The total volume can then be written as

$$V = m_1 v_1 + m_2 v_2; \quad v_i = (\partial V/\partial m_i)_{p,T,m_{j\neq i}} \qquad \text{(A28)}$$

where v_i $(i = 1, 2)$ is the partial specific volume of component i. When component 2 is polymer and component 1 solvent, then, for practical reasons it is convenient to introduce the so-called apparent partial specific volume v_2^* which is defined by

$$V = m_1 v_1^0 + m_2 v_2^* \qquad \text{(A29)}$$

where v_1^0 denotes the specific volume of the solvent. The quantity, v_2^*, now contains the parameter of nonideal mixing of both the solvent and the polymer. In practice, however v_2^* differs not much from v_2 if the polymer concentration is kept low (up to 1%). Dividing Eq. (A29) by the total mass $m_1 + m_2$ leads to

$$v = w_1 v_1^0 + w_2 v_2^* \qquad \text{(A30)}$$

where v is the specific volume of the solution and $w_i = m_i/\sum m_i$ are the mass fractions of the solvent ($i = 1$) and the polymer ($i = 2$).

With $v = 1/\rho$ and $v_1^0 = 1/\rho_1$, ρ and ρ_1 being the densities of the solution and the solvent, respectively, it is readily found that

$$v_2^* = (1/w_2)(\rho_1 - w_1\rho)/(\rho\rho_1) \qquad \text{(A31)}$$

Eq. (A31) demonstrates that v_2^* can be determined by measuring ρ_1 and ρ. Numerous methods for determining densities are described in the literature (268,372–379).

In order to determine the partial specific volume from the apparent specific volume, Eq. (A29) yields

$$(\partial(m_2 v_2^*)/\partial m_2)_{m_1} = m_2(\partial v_2^*/\partial m_2)_{m_1} + v_2^* = (\partial V/\partial m_2)_{m_1} \qquad \text{(A32)}$$

where $(\partial V/\partial m_2)_{m_1}$ is, according to definition, equal to v_2. In terms of mass fractions, Eq. (A32) can finally be written as

$$v_2 = v_2^* + w_1 w_2(\partial v_2^*/\partial w_2) \qquad \text{(A33)}$$

Most values reported in the literature are v_2^*-values rather than v_2-values, since extrapolation according to Eq. (A33) is usually omitted. The differences between v_2^* and v_2 are, however, often small.

1.5. Frictional Ratios The molar frictional coefficient, f_{sp}, of an unsolvated spherical molecule may be computed by the formula based on Stokes law:

$$f_{\mathrm{sp}} = 6\pi\eta R_{\mathrm{H}} N_{\mathrm{A}} = 6\pi\eta[3N_{\mathrm{A}} M v_2/(4\pi)]^{1/3} \qquad \text{(A34)}$$

where η is the viscosity of the solvent and N_{A} is Avogadro's number. When the shape of a molecule deviates from a sphere, or when it is solvated, then the frictional coefficient, f_0, of such a molecule is larger than that of the spherical molecule. The frictional ratio, f_0/f_{sp}, thus permits to draw conclusions concerning either solvation or shape of the

molecule. It is possible to calculate the dimensions of the nonspherical molecule, provided a particular model (ellipsoid, cylinder, etc.) for the molecule is adopted and either the degree of solvation is known or assumed to be negligible. The molar frictional coefficient can be determined either from sedimentation velocity data, provided the molar mass is known from independent measurements according to the Svedberg equation

$$f_0 s_0 = M(1 - v_2\rho_1) \qquad \text{(A35)}$$

or from diffusion measurements, using the relation

$$f_0 = RT/D_0 \qquad \text{(A36)}$$

Eqs. (A34)–(A36) are most frequently used for calculating the frictional ratio. f_0/f_{sp} is listed in the tables. Other relationships for the determination of f_0/f_{sp} are quoted in the literature (2). In these cases special reference to the literature is made in the tables.

In few cases, only the molar frictional coefficient f_0, rather than f_0/f_{sp}, was quoted in the literature. These values are inserted in the same column as the values for the frictional ratio.

1.6. List of Symbols and Abbreviations

Symbols

C	Concentration
C_0	Initial polymer concentration
C_t	Polymer concentration at time t
D	Diffusion coefficient
D_A	Area average of the diffusion coefficient
D_n, D_w, D_z	Number average, mass average, and z-average of the diffusion coefficient
D	Diffusion coefficient at reference temperature and/or pressure
D_0	Diffusion coefficient at zero concentration
η_1	Viscosity of solvent
η_1^θ	Viscosity of solvent at reference temperature and/or pressure
f_{sp}	Molar frictional coefficient of a spherical molecule
f_0	Molar frictional coefficient at zero concentration
k_s, k_s	Concentration coefficients defined by Eq. (A2)
k_D, k_D	Concentration coefficients defined by Eq. (A18)
M	Molar mass of the polymer
M_n, M_w, M_z	Number average, mass average and z-average of the molar mass of the polymer
M	Molar mass determined by Mark–Houwink equation
M_{MW}	Molar mass determined by equations from Mandelkern and Flory, or Wales and Van Holde (see Section 1.7)
$M_{\beta,\gamma}$	Molar mass average determined by Eq. (A26) from $s_{0,\beta}$ and $D_{0,\gamma}$
$M_{s,w}$, $M_{s,A}$, $M_{s,D}$	Molar mass average determined from undefined sedimentation coefficient s and D_w, D_A and undefined diffusion coefficient D, respectively
n	Refractive index or number of moles
ω	Angular velocity
r	Distance from center of rotation
r_0	Distance of meniscus from center of rotation
r_t	Distance of boundary from center of rotation at time t
ρ	Density of solution
ρ_1	Density of the solvent
R	Gas constant
s	Sedimentation coefficient
s_n, s_w, s_z	Number average, mass average, and z-average of the sedimentation coefficient
s_θ	Sedimentation coefficient at reference temperature and/or pressure
s^0	Sedimentation coefficient at pressure $p = 0$ bar
s_0	Sedimentation coefficient at zero concentration
$[s_0]$	Intrinsic sedimentation coefficient (see under Section 1.1)
s_m	Sedimentation coefficient determined from migration of gradient curve median
s_t	Sedimentation coefficient determined from migration of gradient curve maximum
T	Temperature
θ	Theta temperature ($A_2 = 0$)
t	Time
v_i	Partial specific volume of component i ($i = 1$, solvent; $i = 2$, solute)
v_1^0	Specific volume of component i
v_2^*	Apparent specific volume of solute

Abbreviations

A	Archibald method
approx.	approximately

TS	Toyo Soda Co., Japan
V	Number of single values given in Ref. cited

1.7. Miscellaneous With certain assumptions it is possible to determine the molar mass from a combination of the intrinsic viscosity $[\eta]$ and the limiting sedimentation coefficient s_0. In this way, Mandelkern and Flory (128) and Wales and Van Holde (134) derived an expression. An expression similar to the equation between M, $[\eta]$, and s_0 was derived between M, $[\eta]$, and D_0 (128). The molar masses determined from either one of these relationships are refered to as MW.

C. SECOND VIRIAL COEFFICIENTS OF POLYMERS IN SOLUTION

1. Introduction

The behavior of polymers in solution can be described by the colligative properties introducing the virial coefficients A_2, A_3, etc.

According to the theory of McMillan and Mayer (866–868), the second virial coefficient of a monodisperse polymer solution is defined as

$$A_2 = (N_A/(2VM^2)) \int (F_1(1)F_1(2) - F_2(1,2))\,d(1,2) \quad \text{(C1)}$$

where N_A is Avogadro's number, V is the volume of the system, M is the molar mass of the dissoluted polymer, $F_1(1)$, $F_1(2)$, and F_2 (1,2) are the molecular distribution functions of species 1 (solvent molecule) and species 2 (solute molecule), and d(1,2) is the differential volume element in hyperspace. The integral in Eq. (C1) is called the cluster integral. The distribution functions for the molecules, F_1 and F_2, are to be evaluated at zero concentration.

There are a couple of methods for the experimental determination of the second virial coefficient.

1.1. Colligative Properties The vapor pressure depression of the solvent in a polymer solution is expressed as

$$\begin{aligned}(p_1^0 - p_1)/p_1 &= \Delta p_1/p_1 \\ &= V_1^0 C(1/M_n + A_2 C + A_3 C^2 + \cdots)\end{aligned} \quad \text{(C2)}$$

where p_1^0 and p_1 are the vapor pressure of the pure solvent and the solvent in the solution, V_1^0 is the molar volume of the pure solvent, C is the mass concentration of the polymer, M_n is the number average of the molar mass, and $A_2, A_3, \ldots$ are the virial coefficients. For theta conditions, the virial coefficents are zero.

The freezing point depression, $T_{F,1}$, of a polymer solution is

$$T_1^0 - T_1 = \Delta T_{F,1} = E_F C(1/M_n + A_2 C + A_3 C^2 + \cdots) \quad \text{(C3)}$$

and the boiling point increase, $T_{B,1}$, is

$$T_1 - T_1^0 = \Delta T_{B,1} = E_B C(1/M_n + A_2 C + A_3 C^2 + \cdots) \quad \text{(C4)}$$

with T_1^0 and T_1 the boiling point (freezing point) of the pure solvent and of the solvent in the solution, and E_F and E_B are the cryoscopic and ebullioscopic constants.

The osmotic pressure of a polymer solution can be described as

$$\pi = RTC(1/M_n + A_2 C + A_3 C^2 + \cdots) \quad \text{(C5)}$$

where R and T are the gas constant and the absolute temperature. In some cases $B = RTA_2$ is given (instead of A_2).

With certain assumptions it is possible to express the third virial coefficent, A_3, in terms of the second virial coefficient (379–381). Especially when A_2 is small, it is found that, for example, Eq. (C5) can be approximately expressed as (Ref. 382)

$$\pi = (RTC/M_n)(1 + (A_2 M_n/2)C)^2 \quad \text{(C6)}$$

if $A_3 = A_2^2 M_n/4$.

Following Eqs. (C2)–(C6), the dimension of A_2 is given in mol cm^3/g^2 or mol m^3/kg^2.

1.2. Scattering Methods (Classical Light Scattering, X-ray Scattering, Neutron Scattering) Based on the fluctuation theory of Smoluchowski (383) and Einstein (384), which links osmotic pressure with classical light scattering, Debye (385) established the fundamental equation for the light scattering of polymers in solution:

$$KC/R(q) = (M_w p_z(q))^{-1} + 2A_2 Q(q)C + \cdots \quad \text{(C7)}$$

with $q = (4\pi/\lambda)\sin\theta/2$ and

$$p(q) = (2/N^2) \int_0^N (N - n)\sin q h_n / q h_n \,dn$$

Equation (C7) makes it possible to determine the virial coefficients from classical light scattering measurements and can also be applied on X-ray and neutron scattering. In Eq. (C7), K is a constant and $R(q)$ is the excess intensity of the scattered beam at the value q, at unit distance and unit primary intensity. M_w denotes the mass average of the molar mass and $P_z(q)$ is the z-mean of the scattering function from which the dimensions of the dissoluted polymer can be calculated (h_n is the distance between scattering points 0 and n). The $Q(q)$-function corresponds to the q-dependence of A_2. $P(q)$ denotes the scattering function of a monodisperse polymer.

1.3. Sedimentation Velocity The determination of sedimentation and diffusion coefficient, s and D, yields the virial coefficients of a polymer solution (Ref. 800):

$$(D/s)(1 - v_2\rho_1) = RT(1/M + 2A_2 C + 3A_3 C^2 + \cdots) \quad \text{(C8)}$$

where v_2 is the partial specific volume of the solute and ρ_1 is the density of the solvent.

1.4. Sedimentation Equilibrium The sedimentation equilibrium in an ultracentrifuge gives (Ref. 800)

$$\omega^2 r(1 - v_2\rho_1)/(\partial \ln C/\partial r) = RT(1/M + 2A_2C + 3A_3C^2 + \cdots) \tag{C9}$$

where ω is the angular velocity and r is the distance from the center of rotation.

1.5. p–V–T Measurements The virial coefficients are related to thermodynamic quantities

$$A_2 + A_3C + \cdots = -\mu_1^E/(RTC^2V_1) \tag{C10}$$

where V_1 is the partial molar volume of the solvent and μ_1^E is the excess chemical potential of the solvent in the solution.

$$\mu_1^E = (\partial G_m^E/\partial x_1)_{p,T,x_2};\ G_m = G_m^E - G_m^{id} \tag{C11}$$

G_m^E is the molar excess Gibbs energy, G_m is the molar Gibbs energy, and G_m^{id} is the molar Gibbs energy of an ideal solution. With the help of the equation

$$(\partial G_m/\partial p)_{T,x_j} = V_m^E \tag{C12}$$

μ_1^E, and consequently the virial coefficients, can be calculated from p–V–T measurements.

1.6. Averages of the Second Virial Coefficient The average of A_2 for heterogeneous polymers is rather complicated and depends on the measuring method. If A_2 is obtained from measurements based on colligative methods, it will give the average (Ref. 860)

$$A_2^\pi = \int_{i=0}^{\infty}\int_{j=0}^{\infty} A_{ij}\, w(M_i)w(M_j)\, dM_i\, dM_j = (A_2)_{w,w} \tag{C13}$$

This is a double mass average of A_2.

Classical light scattering measurements will give the average (Ref. 860)

$$A_2^{LS} = (1/M_w)^2 \int_0^{\infty}\int_0^{\infty} A_{ij} M_i M_j\, w(M_i)w(M_j)\, dM_i\, dM_j = (A_2)_{z,z} \tag{C14}$$

This is a double z-average of A_2. A_{ij} is defined as

$$A_{ij} = (N_A/(2VM_iM_j)) \int (F_1(i)F_1(j) - F_2(i,j))d(i,j) \tag{C15}$$

where i stands for a molecule of the ith species and j for one of the jth species.

1.7. Second Virial Coefficient – Molar Mass Relationship The dependence of A_2 on the molar mass can be given by a power expression

$$A_2 = K_A M^{a_A} \tag{C16}$$

where K_A and a_A are empirical constants determined for each polymer solvent system at given values of temperature and pressure.

In Section C, relationship (C16) is listed whenever quoted in the literature, in preferences to single A_2 values.

1.8. Temperature Dependence, Pressure Dependence There is no general equation concerning the temperature and pressure dependence. The equation (Ref. 860)

$$A_2 = (N_A/2)(\beta_0/M_0)(1 - \theta/T) \tag{C17}$$

where β_0 is for the independent part of the excluded volume, M_0 is the molar mass of a segment, and θ is the theta temperature, has only a restricted validity.

1.9. Abbreviations

A	Archibald method
approx.	Approximately
CLS	Classical light scattering
DLS	Dynamic light scattering
Cont.	Continued
GPC	Gel permeation chromatography
LALLS	Low angle laser light scattering
OS	Osmotic pressure osmometry
RT	Room temperature
SANS	Small angle neutron scattering
SAXS	Small angle X-ray scattering
SE	Sedimentation equilibrium
SV	Sedimentation velocity
V	Number of single values given in ref. cited
VOS	Vapor pressure osmometry

1.10. Miscellaneous For solvent mixtures, the volume fraction $\varphi_i = v_i/\sum v_i$ is used.

In some cases the second virial coefficient is replaced by $B = RTA_2$.

Several attempts have been made to find theoretical explanations for the nonideal behavior of polymer solutions. There exist numerous excellent books on this topic (272,387,389–398,618,860).

The following tables give second virial coefficients for different polymer solutions. The polymers are arranged according to the hierarchial system in this book. In order to indicate the number of values reported in the original reference, a number, e.g., 5V is given in the column "Remarks". Values for solvent mixtures of different ratios, data for different pH etc., are treated separately in some cases. The user is asked to refer to the original references to find the detailed data and conditions.

A. LIST OF SYMBOLS USED

a_D	exponent in $D = K_D M^{a_D}$
a_s	exponent in $s = K_s M^{a_s}$
$a_{[\eta]}$	exponent in $[\eta] = K_{[\eta]} M^{a_{[\eta]}}$
A_2	second virial coefficient
$\bar{A}_2^{(OP)}$, $\bar{A}_2^{(LS)}$	A_2 from osmotic pressure, light scattering, resp.
B, B', B''	constants
D	diffusion coefficient
$\bar{D}_A$	"area average" diffusion coefficient $\bar{D}_A = \left(\sum_i w_i D_i^{-0.5}\right)^{-2}$
D_i	diffusion coefficient of component i
$\bar{D}_w$	weight-average diffusion coefficient $\bar{D}_w = \sum_i w_i D_i$
$\bar{D}_z$	z-average diffusion coefficient $\bar{D}_z = \left(\sum_i w_i M_i D_i\right) / \left(\sum_i w_i M_i\right)$
$[f]_\Theta$	intrinsic frictional coefficient in the theta state
i	integers 1,2,..., i
k	degree of coupling in Schulz–Zimm distributions of the molecular weight $k = (\bar{M}_w/\bar{M}_n - 1)^{-1}$
K_D	constant in $D = K_D M^{a_D}$
K_0	constant for the determination of unperturbed dimensions $K_0 = \Phi_\Theta(\langle r^2\rangle_0/M)^{3/2}$
K_s	constant in $s = K_s M^{a_s}$
$K_{\langle S^2\rangle}$	constant in $\langle S^2\rangle = K_{\langle S^2\rangle} M^{1+\varepsilon}$
$K_{[\eta]}$	constant in $[\eta] = K_{[\eta]} M^{a_{[\eta]}}$
L	reduced contour length $L = L'/\lambda^{-1}$
L'	contour length
$\bar{L}_n$, $\bar{L}_w$, $\bar{L}_z$	number-, weight-, z-average L
M	molecular weight[1]
$\bar{M}_{av}$	any average of the molecular weight
$\bar{M}_D$	molecular weight from D
M_i	molecular weight of component i
M_j	molecular weight of compound j
$\bar{M}_m$	molecular weight of median in logarithmic normal distributions
$\bar{M}_n$	number-average molecular weight $\bar{M}_n = 1/\sum_i w_i M_i^{-1}$
$\bar{M}_s$	molecular weight from s
$\bar{M}_{\langle S^2\rangle}$	molecular weight from $\langle S^2\rangle$
$\bar{M}_{sD}$	molecular weight from s and D
$\bar{M}_v$	viscosity-average molecular weight $\bar{M}_v = \left(\sum_i w_i M_i^{a_{[\eta]}}\right)^{1/a_{[\eta]}}$
$\bar{M}_w$	weight-average molecular weight $\bar{M}_w = \sum_i w_i M_i$
$\bar{M}_{s[\eta]}$	molecular weight from s and $[\eta]$
$\bar{M}_{[\eta]D}$	molecular weight from $[\eta]$ and D
n_i	mole fraction of component i
N_L	Avogadro number
P_0	constant in $[f]_\Theta = P_0 \langle r^2\rangle_0^{1/2}$
q	polymolecularity correction factor
q_B	q for Baumann–Stockmayer–Fixman procedure
q_{BSF}	q for Burchard–Stockmayer–Fixman equation

[1] According to IUPAC recommendations (1,2), "molecular weight" is understood to be the relative molecular mass, the numerical values of which are identical to those of the molar mass in g/mol and therefore molecular weight is denoted here with the same symbol as the molar mass, viz. M.

q_{BKS}	q for Baumann–Kurata–Stockmayer procedure
$q_{CB,1}, q_{CB,2}$	q's for Cowie–Bywater procedure
q_{Diff}	q for $D = K_D M^{a_D}$
q_{FF}	q for Fox–Flory equation
q_{Gyr}	q for $\langle S^2 \rangle = K_{\langle S^2 \rangle} M^{1+\varepsilon}$
q_{KMSH}	q for $[\eta] = K_{[\eta]} M^{a_{[\eta]}}$
$q(\bar{L}_w)$	q for stiff polymer chains
$q_{\langle r^2 \rangle_n}$	q's for conversion of $[\langle r^2 \rangle^{3/2}]_n^{2/3}$ into $\langle r^2 \rangle_n$,
$q_{\langle r^2 \rangle_w}$	$\langle r^2 \rangle_w$ and
$q_{\langle r^2 \rangle_z}$	$\langle r^2 \rangle_z$, respectively
$q_{\langle S^2 \rangle_w}$	q's for conversion of $\langle S^2 \rangle_z$ into $\langle S^2 \rangle_w$ and
$q_{\langle S^2 \rangle_n}$	$\langle S^2 \rangle_n$, respectively
q_{Sed}	q for $s = K_s M^{a_s}$
$\langle r^2 \rangle$	mean-square end-to-end distance
$\langle r_i^2 \rangle$	$\langle r^2 \rangle$ of component i
$\langle r^2 \rangle_{av}$	any average of $\langle r^2 \rangle$
$\langle r^2 \rangle_0$	mean-square unperturbed end-to-end distance
$\overline{[\langle r^2 \rangle^{3/2}]_n}$	1.5th moment of number distribution of mean-square end-to-end distance $\overline{[\langle r^2 \rangle^{3/2}]_n} = \sum_i n_i \langle r_i^2 \rangle^{3/2}$
$\langle r^2 \rangle_n$	number-average mean-square end-to-end distance $\langle r^2 \rangle_n = \sum_i n_i \langle r_i^2 \rangle$
$\langle r^2 \rangle_w$	weight-average mean-square end-to-end distance $\langle r^2 \rangle_w = \sum_i w_i \langle r_i^2 \rangle$
$\langle r^2 \rangle_z$	z-average mean-square end-to-end distance $\langle r^2 \rangle_z = (\sum_i w_i M_i r_i^2)/(\sum_i w_i M_i)$
s	sedimentation coefficient
$\bar{s}_{max}$	sedimentation coefficient determined from the maximum of the concentration gradient curve
$\bar{s}_w$	weight-average sedimentation coefficient
$\langle S^2 \rangle$	mean-square radius of gyration
$\langle S^2 \rangle_0$	unperturbed mean-square radius of gyration
$\langle S_i^2 \rangle$	$\langle S^2 \rangle$ of component i
$\langle S^2 \rangle_{av}$	any average of $\langle S^2 \rangle$
$\langle S^2 \rangle_n$	number-average mean-square radius of gyration $\langle S^2 \rangle_n = \sum_i n_i \langle S_i^2 \rangle$
$\langle S^2 \rangle_w$	weight-average mean-square radius of gyration $\langle S^2 \rangle_w = \sum_i w_i \langle S_i^2 \rangle$
$\langle S^2 \rangle_z$	z-average mean-square radius of gyration $\langle S^2 \rangle_z = (\sum_i w_i M_i \langle S_i^2 \rangle)/(\sum_i w_i M_i)$
$\langle S^2 \rangle_{0,z}$	unperturbed $\langle S^2 \rangle_z$
v_2	partial specific volume of the solute (index 2)
w_i	mass fraction of component i
w_j	mass fraction of component j
ε	exponent in $\langle S^2 \rangle = K_{\langle S^2 \rangle} M^{1+\varepsilon}$
η	viscosity (index 1: solvent)
$[\eta]$	intrinsic viscosity
$[\eta]_i$	intrinsic viscosity of component i
$[\bar{\eta}]_w$	weight-average intrinsic viscosity $[\bar{\eta}]_w \equiv [\eta] = \sum_i w_i [\eta]_i$
λ^{-1}	length of Kuhn statistical segment
π	pi = 3.14159
ρ	density (index 1: solvent)
σ	standard deviation of logarithmic normal distribution
Θ	index theta state
$\sum_i$	summation over all components i
$\Phi(\varepsilon)$	viscosity function; $\Phi_\Theta = \Phi(\varepsilon = 0) = 2.5 \times 10^{23}\ \mathrm{mol}^{-1}$ for end-to-end distance and $[\eta]$ in cm^3/g is also called Flory constant

B. INTRODUCTION

Relationships between molecular weight M (1,2),[1] and properties dependent on M, for polymers exhibiting a molecular weight distribution (MWD, polymolecularity[2]) require the use of corresponding averages ("principle of corresponding averages" (3)). For example, in Staudinger's viscosity law (4), modified by Kuhn (5), Mark (6), Sakurada (7) and Houwink (8,9) (KMSH), the experimentally determined intrinsic viscosity $[\eta]$ is the weight-average intrinsic viscosity (10–12) but the corresponding molecular weight is the viscosity-average molecular weight (13,14) $\bar{M}_v$:

$$[\eta] = K_{[\eta]} \bar{M}_v^{a_{[\eta]}}$$

where

$$[\eta] = \sum_i w_i [\eta]_i \quad \text{and} \quad \bar{M}_v = \left(\sum_i w_i M_i^{a_{[\eta]}} \right)^{1/a_{[\eta]}}$$

A direct experimental determination of $\bar{M}_v$ is not possible (exception: the intrinsic viscosity $[\bar{\eta}]_\Theta$ and the weight-average sedimentation coefficient $\bar{s}_w$, both for the theta state, inserted in the Flory–Krigbaum–Mandelkern–Scheraga equation (15–17) result in the viscosity-average molecular weight for the theta state, $\bar{M}_{v,\Theta}$ (18)). Therefore, for the determination of the numerical values of the constant $K_{[\eta]}$ and the exponent $a_{[\eta]}$ in Eq. (B1) different molecular weight averages, $\bar{M}_{av}$, are usually applied, e.g. the weight-average molecular weight ($\bar{M}_{av} = \bar{M}_w$), the number-average molecular weight ($\bar{M}_{av} = \bar{M}_n$), or the molecular weight averages obtained with Svedberg's equation[3] (19) $\bar{M}_{sD}$ or the equations of Flory, Krigbaum, Mandelkern and Scheraga (15–17) $\bar{M}_{s[\eta]}$ and $\bar{M}_{[\eta]D}$. From $\bar{M}_{av}$, the viscosity-average molecular weight $\bar{M}_v$ can be calculated, provided the type and width of the molecular weight distribution of the polymer samples or fractions are known (14).

1. Alternatively, a polymolecularity correction factor q can be defined which corrects Eq. (B1) for the use of $\bar{M}_{av}$ instead of $\bar{M}_v$:

$$[\eta] = K_{[\eta]} \bar{M}_v^{a_{[\eta]}} = K_{[\eta]} q_{KMSH} \bar{M}_{av}^{a_{[\eta]}} \qquad \text{(B1)}$$

$$q_{KMSH} = (\bar{M}_v / \bar{M}_{av})^{a_{[\eta]}} \qquad \text{(B2)}$$

Equation (B2) reads, for $\bar{M}_{av} \equiv \bar{M}_w$:

$$q_{KMSH,\bar{M}_w} = \left(\sum_i w_i M_i^{a_{[\eta]}} \right) \bigg/ \left(\sum_i w_i M_i \right)^{a_{[\eta]}} \qquad \text{(B3)}$$

(see Tables 2 and 3).

[2] Polymolecularity is understood to describe the phenomenon that most polymers are nonuniform (2) with respect to relative molecular mass.
[3] See this Handbook page VII–85.

For $\bar{M}_{\mathrm{av}} \equiv \bar{M}_{\mathrm{n}}$:

$$q_{\mathrm{KMSH},\bar{M}_{\mathrm{n}}} = \left(\sum_i w_i M_i^{a_{[\eta]}}\right) \Big/ \left(\sum_i w_i M_i\right)^{a_{[\eta]}} \tag{B4}$$

(see Tables 4 and 5).

For $\bar{M}_{\mathrm{av}} \equiv \bar{M}_{\bar{s}_{\mathrm{w}}\bar{D}_{\mathrm{w}}}$:

$$q_{\mathrm{KMSH},\bar{s}_{\mathrm{w}}\bar{D}_{\mathrm{w}}} = \left(\sum_i w_i M_i^{a_{[\eta]}}\right)\left(\sum_i w_i M_i^{(2-a_{[\eta]})/3}\right)^{-a_{[\eta]}} \times \left(\sum_i w_i M_i^{-(1+a_{[\eta]})/3}\right)^{a_{[\eta]}} \tag{B5}$$

(see Tables 6 and 7).

For $\bar{M}_{\mathrm{av}} \equiv \bar{M}_{\bar{s}_{\mathrm{w}}\bar{D}_{\mathrm{A}}}$:

$$q_{\mathrm{KMSH},\bar{s}_{\mathrm{w}}\bar{D}_{\mathrm{A}}} = \left(\sum_i w_i M_i^{a_{[\eta]}}\right)\left(\sum_i w_i M_i^{(2-a_{[\eta]})/3}\right)^{-a_{[\eta]}} \times \left(\sum_i w_i M_i^{(1+a_{[\eta]})/6}\right)^{-2a_{[\eta]}} \tag{B6}$$

(see Tables 8 and 9).

For $\bar{M}_{\mathrm{av}} \equiv \bar{M}_{\bar{s}_{\mathrm{w}}\bar{D}_{z}}$:

$$q_{\mathrm{KMSH},\bar{s}_{\mathrm{w}}\bar{D}_{z}} = \left(\sum_i w_i M_i^{a_{[\eta]}}\right)\left(\sum_i w_i M_i\right)^{-a_{[\eta]}} \tag{B7}$$

(see Tables 10 and 11).

For $\bar{M}_{\mathrm{av}} \equiv \bar{M}_{\bar{s}_{\mathrm{w}}[\bar{\eta}]_{\mathrm{w}}}$:

$$q_{\mathrm{KMSH},\bar{s}_{\mathrm{w}}[\bar{\eta}]_{\mathrm{w}}} = \left(\sum_i w_i M_i^{a_{[\eta]}}\right)^{1-0.5a_{[\eta]}} \times \left(\sum_i w_i M_i^{(2-a_{[\eta]})/3}\right)^{-1.5a_{[\eta]}} \tag{B8}$$

(see Tables 12 and 13).

For $\bar{M}_{\mathrm{av}} \equiv \bar{M}_{[\bar{\eta}]_{\mathrm{w}}\bar{D}_{\mathrm{w}}}$:

$$q_{\mathrm{KMSH},[\bar{\eta}]_{\mathrm{w}}\bar{D}_{\mathrm{w}}} = \left(\sum_i w_i M_i^{a_{[\eta]}}\right)^{a_{[\eta]}+1}\left(\sum_i w_i M_i^{-(1+a_{[\eta]})/3}\right)^{3a_{[\eta]}} \tag{B9}$$

(see Tables 14 and 15).

For $\bar{M}_{\mathrm{av}} \equiv \bar{M}_{[\bar{\eta}]_{\mathrm{w}}\bar{D}_{\mathrm{A}}}$:

$$q_{\mathrm{KMSH},[\bar{\eta}]_{\mathrm{w}}\bar{D}_{\mathrm{A}}} = \left(\sum_i w_i M_i^{a_{[\eta]}}\right)^{1+a_{[\eta]}}\left(\sum_i w_i M_i^{(1+a_{[\eta]})/6}\right)^{-6a_{[\eta]}} \tag{B10}$$

(see Tables 16 and 17).

For $\bar{M}_{\mathrm{av}} \equiv \bar{M}_{[\bar{\eta}]_{\mathrm{w}}\bar{D}_{z}}$:

$$q_{\mathrm{KMSH},[\bar{\eta}]_{\mathrm{w}}\bar{D}_{z}} = \left(\sum_i w_i M_i^{a_{[\eta]}}\right)^{1+a_{[\eta]}}\left(\sum_i w_i M_i^{(2-a_{[\eta]})/3}\right)^{3a_{[\eta]}} \times \left(\sum_i w_i M_i\right)^{-3a_{[\eta]}} \tag{B11}$$

(see Tables 18 and 19).

2. Correspondingly, polymolecularity correction factors are useful for the relationship of sedimentation coefficient versus molecular weight,

$$s = K_s \bar{M}_s^{a_s} = K_s q_{\mathrm{Sed}} \bar{M}_{\mathrm{av}}^{a_s} \tag{B12}$$

the relationship of diffusion coefficient versus molecular weight,

$$D = K_D \bar{M}_D^{a_D} = K_D q_{\mathrm{Diff}} \bar{M}_{\mathrm{av}}^{a_D} \tag{B13}$$

and the relationship of mean-square radius of gyration[4] versus molecular weight

$$\langle S^2 \rangle = K_{\langle S^2 \rangle} \bar{M}_{\langle S^2 \rangle}^{1+\varepsilon} = K_{\langle S^2 \rangle} q_{\mathrm{Gyr}} \bar{M}_{\mathrm{av}}^{1+\varepsilon} \tag{B14}$$

if other than the corresponding molecular weight averages $\bar{M}_s$, $\bar{M}_D$, and $\bar{M}_{\langle S^2 \rangle}$, respectively (3), are to be used for the numerical evaluation of the constants K_s, K_D, $K_{\langle S^2 \rangle}$ and the exponents a_s, a_D, ε, respectively. Analogous to Eq. (B1) the polymolecularity correction factors for Eqs. (B12), (B13), and (B14) are found to be:

$$q_{\mathrm{Sed}} = (\bar{M}_s / \bar{M}_{\mathrm{av}})^{a_s} \tag{B15}$$

$$q_{\mathrm{Diff}} = (\bar{M}_D / \bar{M}_{\mathrm{av}})^{a_D} \tag{B16}$$

$$q_{\mathrm{Gyr}} = (\bar{M}_{\langle S^2 \rangle} / \bar{M}_{\mathrm{av}})^{1+\varepsilon} \tag{B17}$$

Eq. (B15) reads for $s \equiv \bar{s}_{\mathrm{w}}$, $\bar{M}_{\mathrm{av}} \equiv \bar{M}_{\mathrm{w}}$:

$$q_{\mathrm{Sed},\bar{s}_{\mathrm{w}}\bar{M}_{\mathrm{w}}} = \left(\sum_i w_i M_i^{a_s}\right) \Big/ \left(\sum_i w_i M_i\right)^{a_s} \tag{B18}$$

(see Tables 20 and 21).

For $s \equiv \bar{s}_{\mathrm{w}}$, $\bar{M}_{\mathrm{av}} = \bar{M}_{\mathrm{n}}$:

$$q_{\mathrm{Sed},\bar{s}_{\mathrm{w}}\bar{M}_{\mathrm{n}}} = \left(\sum_i w_i M_i^{a_s}\right)\left(\sum_i w_i / M_i\right)^{a_s} \tag{B19}$$

(see Tables 22 and 23).

[4] The symbol for the radius of gyration is a *capital S* – contrary to the recommendations by IUPAC (2) – in order to distinguish it from the symbol for the sedimentation coefficient s.

For $s \equiv \bar{s}_w$, $\bar{M}_{av} \equiv \bar{M}_{\bar{s}_w \bar{D}_w}$ (20):

$$q_{\mathrm{Sed},\bar{s}_w \bar{M}_{\bar{s}_w \bar{D}_w}} = \left(\sum_i w_i M_i^{-(a_{|\eta|}+1)/3} \right)^{(2-a_{|\eta|})/3} \div \left(\sum_i w_i / M_i^{(2-a_{|\eta|})/3} \right)^{-(1+a_{|\eta|})/3} \quad \text{(B20)}$$

(see Tables 24 and 25).
For calculating $\bar{s}_w$ from experimentally determined $\bar{s}_{max}$, see Tables 26 and 27 (21).

3. Equation (B16) reads for $D \equiv \bar{D}_A$, $\bar{M}_{av} \equiv \bar{M}_n$:

$$q_{\mathrm{Diff},\bar{D}_A \bar{M}_n} = \left(\sum_i w_i M_i^{-a_D/2} \right)^{-2} \left(\sum_i w_i M_i^{-1} \right)^{a_D} \quad \text{(B21)}$$

(see Tables 28 and 29).
For $D \equiv \bar{D}_A$, $\bar{M}_{av} \equiv \bar{M}_{\bar{s}_w \bar{D}_A}$ (20):

$$q_{\mathrm{Diff},\bar{D}_A \bar{M}_{\bar{s}_w \bar{D}_A}} = \left(\sum_i w_i M_i^{(2-a_{|\eta|})/3} \right)^{(a_{|\eta|}+1)/3} \times \left(\sum_i w_i M_i^{(a_{|\eta|}+1)/6} \right)^{2(a_{|\eta|}-2)/3} \quad \text{(B22)}$$

(see Tables 30 and 31).
For $D \equiv \bar{D}_w$, $\bar{M}_{av} \equiv \bar{M}_n$:

$$q_{\mathrm{Diff},\bar{D}_w \bar{M}_n} = \left(\sum_i w_i M_i^{a_D} \right) \left(\sum_i w_i M_i^{-1} \right)^{a_D} \quad \text{(B23)}$$

(see Tables 32 and 33).
For $D \equiv \bar{D}_z$, $\bar{M}_{av} \equiv \bar{M}_n$:

$$q_{\mathrm{Diff},\bar{D}_z \bar{M}_n} = \left(\sum_i w_i M_i^{1+a_D} \right) \left(\sum_i w_i M_i \right)^{-1} \times \left(\sum_i w_i M_i^{-1} \right)^{a_D} \quad \text{(B24)}$$

(see Tables 34 and 35).
For $D \equiv \bar{D}_A$, $\bar{M}_{av} \equiv \bar{M}_w$:

$$q_{\mathrm{Diff},\bar{D}_A \bar{M}_w} = \left(\sum_i w_i M_i^{-a_D/2} \right)^{-2} \left(\sum_i w_i M_i \right)^{-a_D} \quad \text{(B25)}$$

(see Tables 36 and 37).
For $D \equiv \bar{D}_w$, $\bar{M}_{av} \equiv \bar{M}_w$:

$$q_{\mathrm{Diff},\bar{D}_w \bar{M}_w} = \left(\sum_i w_i M_i^{a_D} \right) \left(\sum_i w_i M_i \right)^{-a_D} \quad \text{(B26)}$$

(see Tables 38 and 39).

For $D \equiv \bar{D}_z$, $\bar{M}_{av} \equiv \bar{M}_w$:

$$q_{\mathrm{Diff},\bar{D}_z \bar{M}_w} = \left(\sum_i w_i M_i^{1+a_D} \right) \left(\sum_i w_i M_i \right)^{-(1+a_D)} \quad \text{(B27)}$$

(see Tables 40 and 41).

4. Equation (B17) reads, for $\langle S^2 \rangle \equiv \langle S^2 \rangle_z$, $\bar{M}_{av} \equiv \bar{M}_w$:

$$q_{\mathrm{Gyr},\langle S^2 \rangle_z \bar{M}_w} = \left(\sum_i w_i M_i^{\varepsilon+2} \right) \left(\sum_i w_i M_i \right)^{-(\varepsilon+2)} \quad \text{(B28)}$$

(see Tables 42 and 43).
For $\langle S^2 \rangle \equiv \langle S^2 \rangle_z$, $\bar{M}_{av} \equiv \bar{M}_z$:

$$q_{\mathrm{Gyr},\langle S^2 \rangle_z \bar{M}_z} = \left(\sum_i w_i M_i^{\varepsilon+2} \right) \left(\sum_i w_i M_i \right)^{\varepsilon} \times \left(\sum_i w_i M_i^2 \right)^{-(\varepsilon+1)} \quad \text{(B29)}$$

(see Tables 44 and 45).
For $\langle S^2 \rangle \equiv \langle S^2 \rangle_z$, $\bar{M}_{av} \equiv \bar{M}_n$:

$$q_{\mathrm{Gyr},\langle S^2 \rangle_z \bar{M}_n} = \left(\sum_i w_i M_i^{\varepsilon+2} \right) \left(\sum_i w_i M_i \right)^{-1} \times \left(\sum_i w_i M_i^{-1} \right)^{\varepsilon+1} \quad \text{(B30)}$$

(see Tables 46 and 47).

5. In order to obtain the correct numerical values of constant K_{A_2} and exponent a_{A_2} in the exponential relationship between the second virial coefficient A_2 and molecular weight M

$$A_2 = K_{A_2} M^{a_{A_2}} \quad \text{(B31)}$$

it is necessary to determine the corresponding averages $\bar{A}_{2,av}$ and $\bar{M}_{av}$ with respect to Eq. (B31):

$$\bar{A}_{2,av} = K_{A_2} \bar{M}_{av}^{a_{A_2}} \quad \text{(B32)}$$

$\bar{A}_{2,av}$ is the measured second virial coefficient of a nonuniform (2) polymer sample, while $\bar{M}_{av}$ is the value of the molecular weight which fulfils Eq. (B32) if K_{A_2} and a_{A_2} are valid for strictly uniform (2) samples i:

$$A_{2,i} = K_{A_2} M_i^{a_{A_2}} \quad \text{(B33)}$$

In paper (22), the corresponding averages of the molecular weight $\bar{M}_{av,\bar{A}_2^{(OP)}}$ and $\bar{M}_{av,\bar{A}_2^{(LS)}}$ are calculated for the average second virial coefficients $\bar{A}_2^{(OP)}$ and $\bar{A}_2^{(LS)}$ obtained from

osmotic pressure (OP) and light scattering (LS) measurements, respectively, according to Flory and Krigbaum (23)

$$\bar{A}_2^{(\mathrm{OP})} = \sum_i \sum_j w_i w_j (A_2)_{ij} \tag{B34}$$

$$\bar{A}_2^{(\mathrm{LS})} = (1/\bar{M}_\mathrm{w})^2 \left[\sum_i \sum_j w_i M_i w_j M_j (A_2)_{ij} \right] \tag{B35}$$

where w_i is the mass fraction of uniform polymer species i, w_j the mass fraction of uniform polymer species j, M_i and M_j their molecular weights, respectively, and $(A_2)_{ij}$ is the second virial coefficient effective between species i and j. Since $\bar{M}_{\mathrm{av},\bar{A}_2^{(\mathrm{OP})}}$ and $\bar{M}_{\mathrm{av},\bar{A}_2^{(\mathrm{LS})}}$ are not directly experimentally accessible, polymolecularity correction factors (2) $q_{\bar{M}_\mathrm{n},\bar{A}_2^{(\mathrm{OP})}}$ and $q_{\bar{M}_\mathrm{w},\bar{A}_2^{(\mathrm{LS})}}$ are defined so that $\bar{M}_{\mathrm{av},\bar{A}_2^{(\mathrm{OP})}}$ and $\bar{M}_{\mathrm{av},\bar{A}_2^{(\mathrm{LS})}}$ can be calculated from experimentally determined $\bar{M}_\mathrm{n}$ and $\bar{M}_\mathrm{w}$, respectively:

$$\bar{A}_2^{(\mathrm{OP})} = K_{A_2} \bar{M}^{a_{A_2}}_{\mathrm{av},\bar{A}_2^{(\mathrm{OP})}} = K_{A_2} \bar{M}_\mathrm{n}^{a_{A_2}} q_{\bar{M}_\mathrm{n},\bar{A}_2^{(\mathrm{OP})}} \tag{B36}$$

$$\bar{A}_2^{(\mathrm{LS})} = K_{A_2} \bar{M}^{a_{A_2}}_{\mathrm{av},\bar{A}_2^{(\mathrm{LS})}} = K_{A_2} \bar{M}_\mathrm{w}^{a_{A_2}} q_{\bar{M}_\mathrm{w},\bar{A}_2^{(\mathrm{LS})}} \tag{B37}$$

Thus the respective polymolecularity correction factors

$$q_{\bar{M}_\mathrm{n},\bar{A}_2^{(\mathrm{OP})}} = (\bar{M}_{\mathrm{av},\bar{A}_2^{(\mathrm{OP})}} / \bar{M}_\mathrm{n})^{a_{A_2}} \tag{B38}$$

$$q_{\bar{M}_\mathrm{w},\bar{A}_2^{(\mathrm{LS})}} = (\bar{M}_{\mathrm{av},\bar{A}_2^{(\mathrm{LS})}} / \bar{M}_\mathrm{w})^{a_{A_2}} \tag{B39}$$

can be obtained. The numerical values of $q_{\bar{M}_\mathrm{n},\bar{A}_2^{(\mathrm{OP})}}$ and $q_{\bar{M}_\mathrm{w},\bar{A}_2^{(\mathrm{LS})}}$ are calculated numerically and listed for Schulz–Zimm (SZ), i.e. $q^{(\mathrm{SZ})}_{\bar{M}_\mathrm{n},\bar{A}_2^{(\mathrm{OP})}}$ and $q^{(\mathrm{SZ})}_{\bar{M}_\mathrm{w},\bar{A}_2^{(\mathrm{LS})}}$, and logarithmic normal (LN), i.e. $q^{(\mathrm{LN})}_{\bar{M}_\mathrm{n},\bar{A}_2^{(\mathrm{OP})}}$ and $q^{(\mathrm{LN})}_{\bar{M}_\mathrm{w},\bar{A}_2^{(\mathrm{LS})}}$, distributions of the molecular weight (see Tables 48–51).

6. Similarly, application of the principle of corresponding averages (3,9,24–26) to the relationship of Fox and Flory

$$[\eta] = \Phi(\varepsilon) \frac{\langle r^2 \rangle^{3/2}}{M} \tag{B40}$$

and defining a polymolecularity correction factor q_FF

$$[\eta] = \Phi(\varepsilon) q_\mathrm{FF} \frac{\langle r^2 \rangle^{3/2}_\mathrm{av}}{\bar{M}_\mathrm{av}} \tag{B41}$$

for the use of the z-average mean-square end-to-end distance $\langle r^2 \rangle_\mathrm{z}$ and $\bar{M}_\mathrm{av} \equiv \bar{M}_\mathrm{n}$ in Eq. (B41) leads to

$$q_{\mathrm{FF},\langle r^2 \rangle_\mathrm{z} \bar{M}_\mathrm{n}} = \left(\sum_i w_i M_i^{-1} \right)^{-1} \left(\sum_i w_i M_i^{a_{[\eta]}} \right) \times \left(\sum_i w_i M_i^{(2a_{[\eta]}+5)/3} \right)^{-3/2} \left(\sum_i w_i M_i \right)^{3/2} \tag{B42}$$

(see Tables 52 and 53), whereas for $\langle r^2 \rangle_\mathrm{z}$ and $\bar{M}_\mathrm{av} = \bar{M}_\mathrm{w}$ Eq. (B41) gives

$$q_{\mathrm{FF},\langle r^2 \rangle_\mathrm{z} \bar{M}_\mathrm{w}} = \left(\sum_i w_i M_i \right)^{5/2} \left(\sum_i w_i M_i^{(2a_{[\eta]}+5)/3} \right)^{-3/2} \times \left(\sum_i w_i M_i^{a_{[\eta]}} \right) \tag{B43}$$

(see Tables 54 and 55).

7. For converting the experimentally determined z-average mean-square radius of gyration $\langle S^2 \rangle_\mathrm{z}$ into the weight-average or the number-average mean-square radii of gyration $\langle S^2 \rangle_\mathrm{w}$ or $\langle S^2 \rangle_\mathrm{n}$, respectively

$$\langle S^2 \rangle_\mathrm{w} = q_{\langle S^2 \rangle_\mathrm{w}} \langle S^2 \rangle_\mathrm{z} \tag{B44}$$

$$\langle S^2 \rangle_\mathrm{n} = q_{\langle S^2 \rangle_\mathrm{n}} \langle S^2 \rangle_\mathrm{z} \tag{B45}$$

the polymolecularity correction factors $q_{\langle S^2 \rangle_\mathrm{w}}$ and/or $q_{\langle S^2 \rangle_\mathrm{n}}$

$$q_{\langle S^2 \rangle_\mathrm{w}} = \left(\sum_i w_i M_i^{1+\varepsilon} \right) \left(\sum_i w_i M_i \right) \left(\sum_i w_i M_i^{\varepsilon+2} \right)^{-1} \tag{B46}$$

$$q_{\langle S^2 \rangle_\mathrm{n}} = \left(\sum_i w_i M_i^{\varepsilon} \right) \left(\sum_i w_i M_i^{-1} \right)^{-1} \left(\sum_i w_i M_i^{\varepsilon+2} \right)^{-1} \times \left(\sum_i w_i M_i \right) \tag{B47}$$

are to be used (26) (see Tables 56–59).

8. Correspondingly, in order to convert the 1.5th moment of the number distribution of the mean-square end-to-end distance $[\overline{\langle r^2 \rangle^{3/2}}]_\mathrm{n}$,† resulting from Eq. (B40) if $\bar{M}_\mathrm{n}$ is used (27), into $\langle r^2 \rangle_\mathrm{n}$, $\langle r^2 \rangle_\mathrm{w}$ or $\langle r^2 \rangle_\mathrm{z}$

$$\langle r^2 \rangle_\mathrm{n} = q_{\langle r^2 \rangle_\mathrm{n}} [\overline{\langle r^2 \rangle^{3/2}}]_\mathrm{n}^{2/3} \tag{B48}$$

$$\langle r^2 \rangle_\mathrm{w} = q_{\langle r^2 \rangle_\mathrm{w}} [\overline{\langle r^2 \rangle^{3/2}}]_\mathrm{n}^{2/3} \tag{B49}$$

$$\langle r^2 \rangle_\mathrm{z} = q_{\langle r^2 \rangle_\mathrm{z}} [\overline{\langle r^2 \rangle^{3/2}}]_\mathrm{n}^{2/3} \tag{B50}$$

the polymolecularity correction factors $q_{\langle r^2 \rangle_\mathrm{n}}$, $q_{\langle r^2 \rangle_\mathrm{w}}$, and $q_{\langle r^2 \rangle_\mathrm{z}}$ are to be used:

$$q_{\langle r^2 \rangle_\mathrm{n}} = \left(\sum_i w_i M_i^{(2a_{[\eta]}-1)/3} \right) \left(\sum_i w_i M_i^{-1} \right)^{-1/3} \times \left(\sum_i w_i M_i^{a_{[\eta]}} \right)^{-2/3} \tag{B51}$$

† $[\overline{\langle r^2 \rangle^{3/2}}]_\mathrm{n} = \sum_i n_i \langle r_i^2 \rangle^{3/2} \neq \langle r^2 \rangle_\mathrm{n}^{3/2} = (\sum_i n_i \langle r_i^2 \rangle)^{3/2}$

$$q_{\langle r^2\rangle_w} = \left(\sum_i w_i M_i^{(2a_{[\eta]}+2)/3}\right)\left(\sum_i w_i M_i^{-1}\right)^{2/3} \times \left(\sum_i w_i M_i^{a_{[\eta]}}\right)^{-2/3} \quad \text{(B52)}$$

$$q_{\langle r^2\rangle_z} = \left(\sum_i w_i M_i^{(2a_{[\eta]}+5)/3}\right)\left(\sum_i w_i M_i\right)^{-1} \times \left(\sum_i w_i M_i^{-1}\right)^{2/3}\left(\sum_i w_i M_i^{a_{[\eta]}}\right)^{-2/3} \quad \text{(B53)}$$

(see Tables 60–65).

9. The experimentally obtained ratio of the z-average unperturbed mean-square radius of gyration and the weight-average molecular weight $\langle S^2\rangle_{0,z}/\bar{M}_w$ of a polymolecular sample of stiff polymer chains can be transformed into $\langle S^2\rangle_0/M$ for a monomolecular polymer, the molecular weight M of which is equal to $\bar{M}_w$ of the polymolecular sample, according to:

$$\langle S^2\rangle_0/M = (\langle S^2\rangle_{0,z}/\bar{M}_w)(\bar{M}_w/\bar{M}_z)q(\bar{L}_w) \quad \text{(B54)}$$

where $q(\bar{L}_w)$ is the polymolecularity correction factor (28) (see Tables 66 and 67).

10. Application of the principle of corresponding averages to the various relationships for the experimental determination of the unperturbed dimensions of polymers in thermodynamically good solvents leads unambiguously to the correct polymolecularity correction factors (29).

10.1. The original (30) and modified (31) procedures of Burchard (32), Stockmayer and Fixman (30) can be handled with polymolecularity correction factors q_{BSF} depending upon which average of the molecular weight ($\bar{M}_w$ or $\bar{M}_n$) is to be used (33–35):

$$[\eta]/(q_{BSF,\bar{M}_w}\bar{M}_w^{1/2}) = K_0 + B'\bar{M}_w^{1/2}/q_{BSF,\bar{M}_w} \quad \text{(B55)}$$

$$[\eta]/({}^1q_{BSF,\bar{M}_n}\bar{M}_n^{1/2}) = K_0 + B'\bar{M}_n^{1/2}/{}^2q_{BSF,\bar{M}_n} \quad \text{(B56)}$$

The general formulae for $q_{BSF,\bar{M}_w}$ (33) and for ${}^1q_{BSF,\bar{M}_n}$ and ${}^2q_{BSF,\bar{M}_n}$ (34) were found to be

$$q_{BSF,\bar{M}_w} = \left(\sum_i w_i M_i^{1/2}\right)\left(\sum_i w_i M_i\right)^{-1/2} \quad \text{(B57)}$$

$${}^1q_{BSF,\bar{M}_n} = \left(\sum_i w_i M_i^{1/2}\right)\left(\sum_i w_i M_i^{-1}\right)^{1/2} \quad \text{(B58)}$$

$${}^2q_{BSF,\bar{M}_n} = \left(\sum_i w_i M_i^{1/2}\right)\left(\sum_i w_i M_i^{-1}\right)^{-1/2} \times \left(\sum_i w_i M_i\right)^{-1} \quad \text{(B59)}$$

(see Tables 68–70).

10.2. In the equation of Cowie and Bywater (36) also, two polymolecularity correction factors are necessary. If $\bar{M}_w$ and $\bar{s}_w$ are to be used, one obtains (14,33):

$$(\bar{M}_w^{1/2}/\bar{s}_w)(1-\bar{v}_2\rho_1)/(\eta_1 N_L) = P_0 q_{CB,1} + q_{CB,2}B''\bar{M}_w^{1/2} \quad \text{(B60)}$$

with

$$q_{CB,1} = \left(\sum_i w_i M_i^{1-0.5\varepsilon}\right)\left(\sum_i w_i M_i\right)^{-1/2} \times \left(\sum_i w_i M_i^{0.5(1-\varepsilon)}\right)^{-1} \quad \text{(B61)}$$

$$q_{CB,2} = \left(\sum_i w_i M_i^{1.5-0.5\varepsilon}\right)\left(\sum_i w_i M_i\right)^{-1} \times \left(\sum_i w_i M_i^{0.5(1-\varepsilon)}\right)^{-1} \quad \text{(B62)}$$

(see Tables 71–74).

10.3. Baumann (37) and later Banks and Greenwood (38) describe procedures for the evaluation of unperturbed dimensions from the determination of the molecular weight and the radius of gyration for a series of polymer homologues. The Baumann–Stockmayer–Fixman procedure uses the theory of Stockmayer and Fixman (30) and with the two polymolecularity correction factors $q_{B,\bar{M}_{av}}$ (for the molecular weight) and $q_{B,\langle S^2\rangle_{av}}$ (for the radius of gyration) reads (39):

$$[\langle S^2\rangle_{av} q_{B,\langle S^2\rangle_{av}}/(\bar{M}_{av} q_{B,\bar{M}_{av}})]^{3/2} = K_0^{3/2} + B_{BSF}(\bar{M}_{av} q_{B,\bar{M}_{av}})^{1/2} \quad \text{(B63)}$$

For $\bar{M}_{av} \equiv \bar{M}_w$:

$$q_{B,\bar{M}_w} = \left(\sum_i w_i M_i^3\right)^2\left(\sum_i w_i M_i\right)^{-1}\left(\sum_i w_i M_i^{5/2}\right)^{-2} \quad \text{(B64)}$$

and for $\langle S^2\rangle_{av} \equiv \langle S^2\rangle_z$:

$$q_{B,\langle S^2\rangle_z} = \left(\sum_i w_i M_i^3\right)^2\left(\sum_i w_i M_i\right)\left(\sum_i w_i M_i^{2.5+1.5\varepsilon}\right)^{2/3} \times \left(\sum_i w_i M_i^{5/2}\right)^{-8/3}\left(\sum_i w_i M_i^{2+\varepsilon}\right)^{-1} \quad \text{(B65)}$$

(see Tables 75–78).

10.4. Application of the theory of Kurata and Stockmayer (40) leads to the Baumann–Kurata–Stockmayer procedure (41)

$$\langle S^2\rangle_{\mathrm{av}} q_{\mathrm{BKS},\langle S^2\rangle_{\mathrm{av}}} / (\bar{M}_{\mathrm{av}} q_{\mathrm{BKS},\bar{M}_{\mathrm{av}}}) = K_0 + B_{\mathrm{BKS}} \bar{M}_{\mathrm{av}} q_{\mathrm{BKS},\bar{M}_{\mathrm{av}}} / (\langle S^2\rangle_{\mathrm{av}} q_{\mathrm{BKS},\langle S^2\rangle_{\mathrm{av}}})^{1/2} \quad \text{(B66)}$$

For $\bar{M}_{\mathrm{av}} \equiv \bar{M}_{\mathrm{w}}$:

$$q_{\mathrm{BKS},\bar{M}_{\mathrm{w}}} = \left(\sum_i w_i M_i\right)^{-1} \left(\sum_i w_i M_i^2\right)^{-3} \left(\sum_i w_i M_i^{2+\varepsilon}\right) \times \left(\sum_i w_i M_i^{2.5-0.5\varepsilon}\right)^2 \quad \text{(B67)}$$

and for $\langle S^2\rangle_{\mathrm{av}} \equiv \langle S^2\rangle_{\mathrm{z}}$:

$$q_{\mathrm{BKS},\langle S^2\rangle_{\mathrm{z}}} = \left(\sum_i w_i M_i\right) \left(\sum_i w_i M_i^2\right)^{-4} \left(\sum_i w_i M_i^{2+\varepsilon}\right) \times \left(\sum_i w_i M_i^{2.5-0.5\varepsilon}\right)^2 \quad \text{(B68)}$$

(see Tables 79–82).

The numerical values of the polymolecularity correction factors Eqs. (B3–B11, B18–B30, B42, B43, B46, B47, B51–B53, B57–B59, B61, B62, B64, B65, B67, B68) are tabulated on the following pages for Schulz–Zimm (SZ) distributions of the molecular weight (42,43)

$$w_i(M) = [(k/\bar{M}_{\mathrm{n}})^{k+1}/\Gamma(k+1)] M^k \exp[-(k/\bar{M}_{\mathrm{n}})M] \quad \text{(B69)}$$

and for logarithmic normal (LN) distributions of the molecular weight (44–47)

$$w_i(M) = [1/(\sigma\sqrt{2\pi})] M^{-1} \exp\{-[1/(2\sigma^2)][\log_e(M/\bar{M}_{\mathrm{m}})]^2\} \quad \text{(B70)}$$

as a function of the width of the respective distribution expressed as $\bar{M}_{\mathrm{w}}/\bar{M}_{\mathrm{n}}$ and where relevant of the exponent $a_{[\eta]}$ of Eq. (B1). The calculations have been conducted by inserting Eq. (B69) or Eq. (B70) for SZ or LN, respectively, into the general expressions Eqs. (B3–B11, B18–B30, B42, B43, B46, B47, B51–B53, B57–B59, B61, B62, B64, B65, B67, B68), replacing the summations by integrals and solution of the integrals (48). The resulting formulae of the polymolecularity correction factors $q^{(\mathrm{SZ})}$ and $q^{(\mathrm{LN})}$ are given on the titles of the tables.

Analogously, it is possible to calculate the corresponding formulae for the polymolecularity correctiom factors from the general expressions, Eqs. (B3–B11, B18–B30, B42, B43, B46, B47, B51–B53, B57–B59, B61, B62, B64, B65, B67, B68), for any molecular weight distribution (MWD) of which a closed mathematical expression can be formulated and for which the resulting integrals can be solved. In cases where the MWD is known but no closed mathematical expression can be formulated, or if the resulting integrals cannot be solved analytically, the polymolecularity correction factors nevertheless can be calculated numerically (22,28), i.e. because the general polymolecularity correction formulae represent moments (14) or products of moments of the MWD, they can in principle be taken from any experimentally determined (e.g. by gel-permeation chromatography) molecular weight distribution curve of the polymers or polymer fractions investigated.

In case the type of MWD of the polymers or polymer fractions investigated is not known the numerical values of the following tables still give an appropriate impression of the sensitivity of the methods listed towards type and width of the MWD as compared with the range of the experimental errors. Furthermore, as long as the difference between the numerical values of $q^{(\mathrm{SZ})}$ and $q^{(\mathrm{LN})}$ is not significant, the sensitivity of the method considered toward the type of MWD most probably is not strong, in other words any MWD other than SZ or LN will not exhibit a q value much different from $q^{(\mathrm{SZ})}$ or $q^{(\mathrm{LN})}$. When corresponding numerical values for $q^{(\mathrm{SZ})}$ and $q^{(\mathrm{LN})}$ differ substantially (cf. Tables 75 and 77) and/or $q \gg 1$ (cf. e.g. Table 47) or $q \ll 1$ (cf. e.g. Table 53), it is preferable to look for another experimental method which provides more adequate correction. A closer look upon the numerical values of the following tables also reveals that there are methods which are not sensitive towards polymolecularity (such as setting up $[\eta] = K_{[\eta]} M^{a_{[\eta]}}$ with $\bar{M}_{\bar{s}_{\mathrm{w}}\bar{D}_{\mathrm{A}}}$ (Tables 8 and 9) whereas others are very sensitive towards polymolecularity (such as correlating $\bar{D}_{\mathrm{z}}$ and $\bar{M}_{\mathrm{n}}$ in $D = K_D M^{a_D}$ (Tables 34 and 35)).

The exponents $a_{[\eta]}$, a_s, a_D, ε, and a_{A_2} of Eqs. B1, B12–B14 and B31 are interconnected with each other (49–55) by the "Exponents' Rule" (50,14):

$$a_{[\eta]} = 2 - 3a_s = -(1 + 3a_D) = 1.5\varepsilon + 0.5 = a_{A_2} + 1$$

In the following tables the numerical values for $\bar{M}_{\mathrm{w}}/\bar{M}_{\mathrm{n}}$ range from 1.1 to 20.0, those for $a_{[\eta]}$ from 0.4 to 0.9, in order to cover also limiting cases which occur in practical work (e.g., $a_{[\eta]} < 0.5; \varepsilon < 0$). The intervals for both parameters $\bar{M}_{\mathrm{w}}/\bar{M}_{\mathrm{n}}$ and $a_{[\eta]}$ as well as the number of digits behind the decimal sign for the polymolecularity correction factors are chosen so that for any value of $\bar{M}_{\mathrm{w}}/\bar{M}_{\mathrm{n}}$ and $a_{[\eta]}$ within the above-mentioned limits the numerical value of the polymolecularity correction factor can be found by interpolation of the numerical values given in the tables with an accuracy of at least about 1% except, of course, when extremely low numerical values are involved. In order to enable the user to calculate the numerical values of the polymolecularity correction factors for any $\bar{M}_{\mathrm{w}}/\bar{M}_{\mathrm{n}}$ and $a_{[\eta]}$ (or a_s, a_D, ε, and a_{A_2}, respectively) the exact formulae for all polymolecularity correction factors tabulated are given on top of the corresponding tables; for this purpose a table of the numerical values of the gamma function $\Gamma(x)$ for $1.00 \le x \le 2.00$ is included

(Table 1). For $x < 1$ and $x > 2$, the following formula can be used

$$\Gamma(x+1) = x\Gamma(x)$$

TABLE 1. NUMERICAL VALUES OF GAMMA FUNCTION $\Gamma(x)$

x	$\Gamma(x)$	x	$\Gamma(x)$	x	$\Gamma(x)$	x	$\Gamma(x)$

A. INTRODUCTION

The classical thermodynamics of binary polymer–solvent systems was developed independently by P. J. Flory (1–3) and M. L. Huggins (4–6). It is based on the well-known lattice model qualitatively formulated by K. H. Meyer (7), who pointed out the effect of the differences in molecular size of polymer and solvent molecules on the entropy of mixing. The quantitative calculation of the entropy of mixing led to the introduction of a dimensionless quantity, the so-called Flory–Huggins interaction parameter χ, for the thermodynamic description of polymer solutions.

It was evident from the beginning that χ is a function of T; however, at first χ was considered to be independent of the concentration of the polymer. Subsequent experiments have shown the necessity of treating χ as a function of composition (8,9). Furthermore, χ also depends on M_2 (the molecular weight of the polymer), not only at high dilution, but – according to recent experiments (10) – even at high concentrations of polymers.

B. CONCENTRATION VARIABLES

Since the numerical value of the interaction parameter depends on the concentration variable chosen, one has to specify it in each case. The following three quantities are most frequently used, where the subscript 1 stands for the solvent and the subscript 2 for the polymer:

1. Volume fractions φ_i:

$$\varphi_2 = \frac{n_2 V_2}{n_1 V_1 + n_2 V_2} \tag{B1}$$

n_i moles of component i
V_i molar volume of component i

2. Weight fractions w_i:

$$w_2 = \frac{m_2}{m_1 + m_2} \tag{B2}$$

m_i weight of component i

3. Segment fractions s_i (hard core volume fractions):

$$s_2 = \frac{n_2 V_2^*}{n_1 V_1^* + n_2 V_2^*} \tag{B3}$$

V_i^* molar hard core volume (characteristic volumes) of components related to reduced volumes $\tilde{V}_i$ by $\tilde{V}_i = V_i/V_i^*$ (11).

C. CONVERSION OF CONCENTRATION VARIABLES

	φ_2	w_2	s_2
φ_2	–	$w_2 \frac{\rho}{\rho_2}$	$s_2 \frac{\tilde{V}_2}{\tilde{V}}$
w_2	$\varphi_2 \frac{\rho_2}{\rho}$	–	$s_2 \frac{\rho_2^*}{\rho^*}$
s_2	$\varphi_2 \frac{\tilde{V}}{\tilde{V}_2}$	$w_2 \frac{\rho^*}{\rho_2^*}$	–

ρ, ρ_i are the densities of the solution and of the pure component i, $1/\rho = w_1/\rho_1 + w_2/\rho_2$;
ρ^*, ρ_i^* are the hard core (characteristic) densities of the solution and of the component i, $\rho_i^* = M_i/V_i^*$ where M_i is the molar mass, $1/\rho^* = w_1/\rho_1^* + w_2/\rho_2^*$;
$\tilde{V}$, $\tilde{V}_i$ are the reduced volumes of the solution and of the component i.

D. BASIC EQUATIONS

The reduced molar Gibbs energy of mixing, $\Delta G_M/RT$, is given by the following equation:

$$\frac{\Delta G_M}{RT} = x_1 \ln \varphi_1 + x_2 \ln \varphi_2 + g x_1 \varphi_2 \tag{D1}$$

where x_i is the mole fraction of component i, R is the gas constant, T is the absolute temperature and g stands for the integral polymer–solvent interaction parameter; g refers to the interaction (mixing of the pure liquid compounds) of a solvent molecule with a polymer segment, the size of which is defined by the molar volume of the solvent. This definition implies some difficulties as soon as mixed solvents or solvents with more than one segment are considered.

Alternatively, the Gibbs energy of mixing can be normalized to the volume, so that it reads

$$\frac{\Delta G_M}{V} = \frac{RT}{V_1}\varphi_1 \ln \varphi_1 + \frac{RT}{V_2}\varphi_2 \ln \varphi_2 + B\varphi_1\varphi_2 \qquad \text{(D2)}$$

where B is an interaction energy–density parameter that no longer depends on the definition of a segment, and relates to g and molar volume of the segment V_{seg} by

$$B = RT\frac{g}{V_{seg}} \qquad \text{(D3)}$$

The sum

$$x_1 \ln \varphi_1 + x_2 \ln \varphi_2 = \frac{\Delta G_M^{comb}}{RT} \qquad \text{(D4)}$$

of Eq. (D1) is the combinatorial part of ΔG_M. The remaining term

$$g x_1 \varphi_2 = \frac{\Delta G_M^R}{RT} \qquad \text{(D5)}$$

is the so-called reduced residual Gibbs energy of mixing.

Partial differentiation of $\Delta G/RT$ with respect to n_1, the number of moles of solvent, or n_2, the number of moles of polymer, respectively, yields the reduced partial molar Gibbs energy of mixing of the solvent $\Delta G_1/RT = \Delta\mu_1/RT$, or the reduced partial molar Gibbs energy of mixing of the polymer, $\Delta G_2/RT = \Delta\mu_2/RT$:

$$\frac{\Delta G_1}{RT} = \frac{\Delta\mu_1}{RT} = \ln(1-\varphi_2) + \left(1 - \frac{1}{N}\right)\varphi_2 + \chi\varphi_2^2 \qquad \text{(D6)}$$

$$\frac{\Delta G_2}{RT} = \frac{\Delta\mu_2}{RT} = \ln(1-\varphi_1) + (1-N)\varphi_1 + \xi N\varphi_1^2 \qquad \text{(D7)}$$

$N = V_2/V_1$ (where $V_1 = V_{seg}$), the ratio of the molar volumes of the components is, in general, different from the degree of polymerization but proportional to it; χ and ξ are the Flory–Huggins interaction parameters in the differential equation for the solvent and for the polymer, respectively.

Separating ΔG_1 and ΔG_2 like ΔG_M (Eqs. D1–D5) into a combinatorial and a residual contribution yields the following expressions for the different interaction parameters, which demonstrates that they measure the deviation of a real polymer solution from purely combinatorial behavior:

$$g = \frac{\Delta G_M^R}{RTx_1\varphi_2} \qquad \text{(D8)}$$

$$\chi = \frac{\Delta G_1^R}{RT\varphi_2^2} \qquad \text{(D9)}$$

$$\xi = \frac{\Delta G_2^R}{RTN\varphi_1^2} \qquad \text{(D10)}$$

From phenomenological thermodynamics, one obtains the interrelations between these parameters, given in Eqs. (D11–D13):

$$g = \varphi_2\chi + (1-\varphi_2)\xi = \frac{1}{\varphi_1}\int_0^{\varphi_1} \chi d\varphi_1 \qquad \text{(D11)}$$

$$\chi = g + \varphi_1\frac{\partial g}{\partial \varphi_1} = g - (1-\varphi_2)\frac{\partial g}{\partial \varphi_2} \qquad \text{(D12)}$$

$$\xi = g + \varphi_2\frac{\partial g}{\partial \varphi_2} \qquad \text{(D13)}$$

Since it is the chemical potential of the solvent that is normally measured, χ is practically the only interaction parameter that can be directly obtained. In the following text, the term polymer–solvent interaction parameter (Flory–Huggins parameter) is, therefore, exclusively applied to χ.

E. METHODS OF DETERMINATION

Rearrangement of Eq. (D6) yields

$$\chi = \frac{\Delta G_1^R}{RT\varphi_2^2} = \frac{\Delta G_1}{RT\varphi_2^2} - \frac{1}{\varphi_2^2}\left(\ln(1-\varphi_2) + \left(1-\frac{1}{N}\right)\varphi_2\right) \qquad \text{(E1)}$$

METHODS FOR THE DETERMINATION OF POLYMER–SOLVENT INTERACTION PARAMETERS

Typical range of concentration	Methods	Abbreviation in text	Refs.
$\varphi_2 \to 0$	Scattering methods	LS	20
		SAXS	129
		SANS	
$0 < \varphi_2 < 0.3$	Osmosis	OS	21–25
	Light scattering	LS	
	Critical miscibility (only applicable with poor solvents)	CM	
	Differential vapor–pressure methods	ΔVP	26
$0.3 < \varphi_2 < 0.8$	Vapor–pressure methods	VP	3
$\varphi_2 \to 1$	Inverse gas chromatography (gas liquid chromatography)	IGC	27–30

Since $\Delta G_1 = RT \ln a_1$, the interaction parameter χ is accessible from the measured activity of the solvent. In order to get the information for the entire range of concentrations, a combination of several methods is necessary. The table given on the previous page shows the concentration ranges for the applicability of the most commonly used methods, the abbreviations used in the text to specify the method, and some pertinent references. Information stemming from the following sources is not incorporated in the tables: melting point depression of polymer (3,12,13), freezing point depression of solvents (8), swelling equilibria (3,14–17), and intrinsic viscosities (18,19).

F. TEMPERATURE DEPENDENCE

The temperature dependence of χ can be described for most systems exhibiting UCSTs by means of the following equation:

$$\chi(T) = a + \frac{b}{T} \quad \text{(F1)}$$

Knowing the temperature dependence of χ, it is possible to split this quantity in its enthalpic and entropic part (χ_H and χ_S).

$$\chi = \chi_H + \chi_S \quad \text{(F2)}$$

where

$$\chi_H = -T\left(\frac{\partial \chi}{\partial T}\right)_{p,\varphi_2} = \frac{\Delta H_1^R}{RT\varphi_2^2} \quad \text{(F3)}$$

$$\chi_S = \left(\frac{\partial (T\chi)}{\partial T}\right)_{p,\varphi_2} = \frac{\Delta S_1^R}{R\varphi_2^2} \quad \text{(F4)}$$

G. CONCENTRATION DEPENDENCE

The following expression for the Flory–Huggins parameter was deduced on the basis of the lattice theory (25):

$$\chi = \alpha + \frac{\beta(1-\gamma)}{(1-\gamma\varphi_2)^2} \quad \text{(G1)}$$

where α and γ are constants within a certain temperature range and β varies with T ($\beta = \beta_0 + \beta_1/T$).

For the integral interaction parameter, g, the equation reads:

$$g = \alpha + \frac{\beta}{(1-\gamma\varphi_2)} \quad \text{(G2)}$$

For an analytical representation of the experimentally found concentration dependence, the following power series with $n = 2$ is normally adequate:

$$\chi = \sum_{i=0}^{n} \chi_i \varphi_2^i \quad \text{(G3)}$$

$$g = \sum_{i=0}^{n} \frac{\chi_i}{i+1} \frac{1-\varphi_2^{i+1}}{1-\varphi_2} \quad \text{(G4)}$$

According to experimental information, three characteristic behaviors can be distinguished:

1. Very often, χ increases greatly with polymer concentration, particularly in the case of poor solvents. The systems benzene/polyisobutylene (PIB) (21,31,32), n-pentane/polyisobutylene (33,34), and cyclohexane/polystyrene (22) (Figs. 1 and 2) constitute examples.

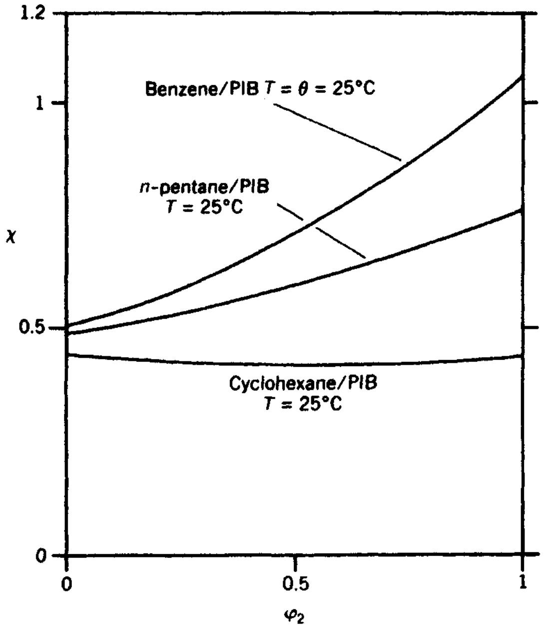

Figure 1. Examples for the variation of the Flory–Huggins interaction parameter, χ (Eq. D14), with the volume fraction φ_2 of polymer for the systems benzene/poly(isobutylene) (PIB), n-pentane/PIB and cyclohexane/PIB at the indicated temperatures.

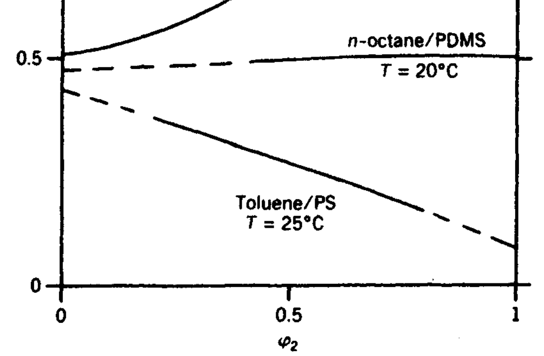

Figure 2. Examples for the variation of the Flory–Huggins interaction parameter, χ (Eq. D14), with the volume fraction φ_2 of polymer for the systems cyclohexane/polystyrene (PS), n-octane/poly(dimethyl siloxane) (PDMS) and toluene/PS at the indicated temperatures.

COEFFICIENTS χ_0, χ_1, χ_2 (Eq. G3) OF SYSTEMS SELECTED FOR GRAPHICAL REPRESENTATION (Figs. 1 AND 2)

System	T/(°C)	χ_0	χ_1	χ_2	Refs.
Benzene/PIB	25	0.506	0.229	0.317	21,31,32
n-Pentane/PIB	25	0.484	0.184	0.080	33,34
Cyclohexane/PIB	25	0.440	−0.083	0.068	30,31,35
Cyclohexane/PS	34	0.507	0.149	0.464	22
n-Octane/PDMS	20	0.501	−0.035	0.042	36
Toluene/PS	25	0.431	−0.311	−0.036	37

2. In some cases, χ seems to be independent of composition, as proposed by the original Flory–Huggins theory. These findings mainly concern good solvents; examples are the systems cyclohexane/polyisobutylene (30,31,35) and *n*-octane/poly(dimethyl siloxane) (PDMS) (36) (Figs. 1 and 2).
3. In a few cases, mostly with highly exothermal systems, χ decreases with concentration, as with toluene/polystyrene (37) (Fig. 2).

The lines drawn in Figs. 1 and 2 have been calculated by means of Eq. (G3) and the coefficients χ_i, collected in the table given above.

H. MOLECULAR WEIGHT DEPENDENCE

Second osmotic virial coefficients, as obtained from osmotic pressure or light scattering measurements with dilute polymer solutions, depend markedly on M_2; since this quantity is closely related (cf. Eq. I1) to χ, its dependence on chain length in this concentration regime is obvious. Recent experiments (10) have shown that χ may depend on the molar mass of the polymer even for concentrated solutions. Furthermore, there is some evidence (given in Ref. 60, resulting from a common valuation of the data given in Refs. 83,58,33,30 and 90, and from a comparison of the results reported in Refs. 99 and 110) that even χ_∞, the χ parameter for an infinitely large excess of polymer, may depend on chain length. According to the few presently available experimental data, a reduction of χ upon an increase of M_2 according to some scaling law seems to be the normal case.

I. POLYMER-SOLVENT INTERACTION PARAMETERS, χ

Values of the polymer–solvent interaction parameters, defined by Eq. (E1) in terms of volume fractions, have been collected. They are tabulated as a function of polymer concentration for various temperatures. Data given on the basis of segment fractions, s_2, or weight fractions, w_2, were converted into volume fractions φ_2.

If needed, χ_0 can be calculated from the second osmotic virial coefficient A_2 (see corresponding chapter in this Handbook by means of the following equation:

$$\chi_0 = 0.5 - \rho_2^2 V_1 A_2 \qquad \text{(I1)}$$

A. INTRODUCTION

The dependence of the viscosity of dilute polymer solutions on concentration can be described by a power series:

$$\eta = \eta_0(1 + a_1c + a_2c^2 + a_3c^3 + \cdots) \qquad \text{(A1)}$$

where η is the viscosity of the solution and η_0 is the viscosity of the solvent. This equation is usually presented in another form:

$$\eta = \eta_0(1 + [\eta]c + k_1[\eta]^2c^2 + k_2[\eta]^3c^3 + \cdots) \qquad \text{(A2)}$$

where $[\eta]$ is the limiting viscosity number and $k_i(k_1, k_2, \cdots)$ is a dimensionless constant. If terms with the third and higher powers of concentration are neglected, then Eq. (A2) becomes

$$\eta = \eta_0(1 + [\eta]c + k_1[\eta]^2c^2) \qquad \text{(A3)}$$

which, since $\eta/\eta_0 = \eta_{\rm rel}$ (viscosity ratio) and $\eta_{\rm rel} - 1 = \eta_{\rm sp}$ (specific viscosity), can be put in the form

$$\eta_{\rm sp} = [\eta]c + k_1[\eta]^2c^2 \qquad \text{(A4)}$$

which becomes the Huggins equation (1)

$$\eta_{\rm sp}/c = [\eta](1 + k_{\rm h}[\eta]c) \qquad \text{(A5)}$$

where $k_{\rm h}$ is the Huggins viscosity constant that is the most commonly used dilute solution viscosity number or index. It is easily determined from the slope of a plot of $\eta_{\rm sp}/c$ versus c.

The Huggins constant can be thought of as a measure of the "goodness" of the solvent for the polymer with values around 0.3 in good solvents and 0.5–1 in theta solvents. It should be noted that these generalizations break down with extremely dilute solutions (2) and with chain aggregation (3). In both cases, values tend to be higher. The Huggins constant is independent of molecular weight for many polymers, but is dependent on molecular weight for polymers that associate easily in solution (3).

The Huggins equation and Huggins constants can be used to determine values for the limiting viscosity number, $[\eta]$. For extrapolation procedures related to $[\eta]$ and $k_{\rm h}$, see (Ref. 4). Applications of the Huggins equation to measure $[\eta]$ are given in Refs. (5,6). The latter gives an equation for $[\eta]$:

$$[\eta] = \frac{(1 + 4k_{\rm h}\eta_{\rm sp})^{1/2} - 1}{2k_{\rm h}c} \qquad \text{(A6)}$$

which can be used for single point determinations, i.e., calculating $[\eta]$ from a single viscosity measurement at a known concentration. Computer programs relating solution viscosity and molecular parameters are found in Refs. (7,8).

Other semiempirical equations, such as those of Kraemer and Schulz and Blaschke, also are used for processing viscosity data. The Kraemer equation (Ref. 9) is

$$\ln \eta_{\rm rel}/c = [\eta](1 - k_{\rm k}[\eta]c) \qquad \text{(A7)}$$

where k_k is the Kraemer constant. Sometimes, the term $k_k[\eta]c$ is written as positive and the constants are listed as negative numbers. The result is the same. The Schulz–Blaschke equation (10) is

$$\eta_{sp}/c = [\eta](1 + k_{sb}\eta_{sp}) \qquad \text{(A8)}$$

Although few Schulz–Blaschke constants have been published, some investigators contend that the Schulz–Blaschke equation is superior because it works with a wider range of concentrations and is not bound to a constant specific viscosity region (11). On the other hand, it is not recommended for single point determinations because of large errors (6). Huggins' and Kraemer's equations, used singly or in combined form, are better (6).

In addition to the polymer–solvent system, k_h and k_{sb} depend on concentration (whether semidilute, dilute, or extremely dilute), molecular weight, degree of branching, shear rate of measurement, and whether there can be preferential solvation (copolymers and mixed solvents). With polymers in good solvents, measured values for the Huggins constant are between 0.3 and 0.4. In some cases, they are even lower (2). With decreasing goodness of the solvent, the Huggins constant increases steadily, reaching 0.55 or more for theta conditions.

Regarding concentration, deGennes (12) has defined a critical concentration, c^*, above which solutions are semidilute and below which they are dilute. Most k_h and k_{sb} values have been measured in the dilute region. Dondos (2) has defined another critical concentration, c^{**}, below which the solution is called extremely dilute. Values for k_h measured below c^{**} tend to be higher than those measured between c^* and c^{**}. It is interesting that Peterson and Fixman (13) predicted higher values for Huggins constants except for those below c^{**}. It may be that the low values in the dilute region are due to polymer coil compression because of lack of sufficient volume (2).

The Huggins constant is not supposed to be dependent on the molecular weight of the polymer. In many cases, it is not (14–18), or the dependence is small (14,19,20), but other results show definite molecular weight dependence (3,21). It appears that the Huggins constant is related to molecular weight in polymers that associate in solution, either by the effect of strong ionic or polar interactions, or by the effect of hydrogen bonds (3).

There is a relationship between k_h and the coil expansion factor or coefficient of expansion, α, which is a measure of the extent of the expansion of the polymer coil in a particular solvent. In good solvents, the coil is more extended than in poor solvents and α is correspondingly larger. The Huggins constant seems to vary with α^3 (3,14,22,23). One expression for this is (Ref. 23)

$$k_h = a + b\alpha^3 + c \qquad \text{(A9)}$$

Although there is no agreement in the literature as regards the influence of branching on viscosity constants, most results indicate that k_h and k_{sb} increase with higher degrees of branching (24–26). There is no agreement on the effect of shearing on viscosity constants either, the literature indicating both increases (27) and decreases (28) with increasing shear rate. Shearing that produced chain scission lowered the limiting viscosity number $[\eta]$ and raised k_h, and did so more at higher shear rates, although there was a tendency toward stabilization at the highest shear rates (29). The influence of shear rate is usually neglected below 1500 sec^{-1} (11).

Huggins constants also can be determined for dilute suspensions. The k_h value for such a suspension is sensitive to the degree and nature of the polydispersity of the specimen (30).

The following tables contain Huggins and Schulz–Blaschke constants taken from the literature, along with the relevant references. The values are listed by limiting viscosity number $[\eta]$, the units of which are ml/g. Values marked with an asterisk (*) are interpolated values from the literature (mostly mean values calculated by Stickler and Sutterlin (11)). For information on molecular weight and other factors, as well as conditions of measurement not given in the tables, the reader may refer to the original publications.

A. INTRODUCTION

1. Fundamentals

1.1 Thermodynamics The theta state is defined as that state of a polymer solution at which the excess chemical potential, and correspondingly, the excess Gibbs energy of dilution is zero. For a given polymer–solvent system, this state is obtained at a certain characteristic temperature, the theta temperature Θ. A solvent at this temperature is called a theta solvent.

Since Flory (110) was the first to show the importance of the theta state for a better understanding of physical structures and properties of polymers, the theta temperature is sometimes also called "Flory temperature". The name "van't Hoff temperature" has also been suggested (127). However, neither "Flory temperature" nor "van't Hoff temperature" has gained acceptance.

The exact definition of the theta state is given by chemical thermodynamics. The chemical potential of a solvent 1, $\Delta\mu_1$, can be split into an ideal term and an excess term:

$$\Delta\mu_1 = \Delta\mu_1^{\mathrm{id}} + \Delta\mu_1^{\mathrm{exc}} \qquad \text{(A1)}$$

where the excess chemical potential at the thermodynamic temperature T is given by the enthalpy of dilution, ΔH_1, and the excess entropy of dilution, $\Delta S_1^{\mathrm{exc}}$:

$$\Delta\mu_1^{\mathrm{exc}} = \Delta H_1 - T\Delta S_1^{\mathrm{exc}} \qquad \text{(A2)}$$

A zero excess chemical potential does not imply that both the enthalpy of solution and the excess entropy of solution are zero as in the case of true ideal solutions where $\Delta H_1 \equiv 0$ and $\Delta S_1^{\mathrm{exc}} = 0$. Rather, a theta state means only that the terms on the right side of Eq. (A2) compensate each other at the theta temperature Θ, i.e., $\Delta H_1 \equiv \Theta\Delta S_1^{\mathrm{exc}}$ for $\Delta\mu_1^{\mathrm{exc}}$ at $T = \Theta$. Solutions in the theta state are thus not thermodynamically ideal but thermodynamically pseudo-ideal (306).

The chemical potential cannot be measured directly. It may be expressed, however, by the product of the osmotic pressure Π of the solution and the partial specific volume $^*\mathrm{v}_1$ of the solvent:

$$-\Delta\mu_1 = {}^*\mathrm{v}_1\Pi \qquad \text{(A3)}$$

The concentration dependence of the osmotic pressure of non-electrolyte solutions can be written as a power series

$$\Pi = A_1c_2 + A_2c_2^2 + A_3c_2^3 + \cdots \qquad \text{(A4)}$$

where $c_2 = m_2/V$ is the mass concentration of the polymer (mass m_2 of the polymer 2 per total volume V of the solution *after* mixing polymer and solvent) and A_1, A_2, $A_3, \ldots$ are first, second, third,... virial coefficients, respectively. The second virial coefficient is a measure of the interaction between two bodies, the third virial coefficient a measure of interactions between three bodies, etc. Second and third virial coefficients depend on the chemical structure and the molar mass of the polymer, the chemical structure of the solvent (and thus its interaction with the polymer), and the temperature.

The first virial coefficient is given by

$$A_1 = RT/\overline{M}_n \tag{A5}$$

where R is the general gas constant ($R = 8.314510$ J/K/mol) and $\overline{M}_n$ is the number-average molar mass of the polymer. Eq. (A4) is thus often written as

$$\frac{1}{(\overline{M}_n)_{app}} \equiv \frac{\Pi}{RTc_2} = \frac{1}{\overline{M}_n} + Bc_2 + Cc_2^2 + \cdots \tag{A6}$$

where $(\overline{M}_n)_{app}$ is the apparent number-average molar mass, $B = A_2/RT$, and $C = A_3/RT$.

The third term of the right-hand side of Eq. (A4) is often negligible at low polymer concentrations. Combinations of Eqs. (A1), (A3) and (A4) then yields,

$$A_2 = -\Delta\mu_1^{exc}/({}^*v_1 c_2^2) \tag{A7}$$

Since by definition the excess chemical potential is zero at the theta temperature, the second virial coefficient (but not necessarily the third virial coefficient) is also zero ($A_2 = 0$ at $T = \Theta$). The concentration dependence of the reduced osmotic pressure, Π/c_2, is thus zero at the theta temperature, albeit at low concentrations only. The same reasoning applies to other colligative methods (cryoscopy, ebullioscopy, vapor phase osmometry) and also to those physical methods that measure concentration dependencies of apparent molar masses (static light scattering, sedimentation equilibrium, combination of sedimentation and diffusion coefficient, etc.). An example is static light scattering which yields at the scattering angle $\vartheta \to 0°$:

$$\frac{1}{(\overline{M}_w)_{app}} \equiv \frac{K_0 c_2}{R_0} = \frac{1}{\overline{M}_w} + 2Bc_2 + 3Cc_2^2 + \cdots \tag{A8}$$

where $(\overline{M}_w)_{app}$ = apparent mass-average molar mass, K_0 = optical constant at zero angle, and R_0 = Rayleigh ratio at zero scattering angle. The virial coefficients B and C of light scattering average differently over interactions than those of colligative measurements; B and C of polymolecular ("polydisperse") polymers are numerically different for osmotic pressure and light scattering measurements.

The theta temperature may also be phenomenologically defined as the critical miscibility temperature at the limit of infinite molar mass (110). Since a solution may exhibit two critical miscibility temperatures, a polymer solution may display two theta temperatures. In the case of endothermic solutions, a lowering of temperature leads to less positive second virial coefficients and the theta temperature corresponds to an upper critical solution temperature (UCST) in the limit of infinite molar mass. The theta temperature corresponds to a lower critical solution temperature (LCST) in the case of exothermic solutions (see, e.g., (92)).

1.2. Unperturbed Dimensions The thermodynamic behavior described above results from the fact that long-range interactions between polymer segments are absent in the theta state. Long-range interactions are intramolecular interactions between segments or groups of one and the same polymer molecule that are separated by many chemical bonds along the chain; they are remote in sequence but adjacent in space. Short-range interactions are interactions between chain groups that are near to each other in sequence. They are determined by the length of chain bonds, the valence angles between chain atoms, and the hindrance to rotation around chain bonds (usually due to a pair (4 chain bonds) or two pairs (5 chain bonds) of conformers in the chain).

In a thermodynamically good solvent ($A_2 \gg 0$), polymer–solvent interactions are much larger than polymer–polymer and solvent–solvent interactions. The polymer chain expands in order to minimize polymer–polymer contacts; the dimensions of these chains are said to be perturbed. In such perturbed chains, the space occupied by one polymer segment is excluded for all other segments of the same polymer chain, i.e., even at infinite dilution.

In a theta solvent ($A_2 = 0$), polymer–solvent interactions are just balanced by polymer–polymer and solvent–solvent interactions. Long-range interactions disappear and the polymer chain assumes its so-called unperturbed dimensions which manifest themselves for linear chains by a dependence of the root-mean square radii of gyration s, on the square root of molar masses:

$$\langle s^2 \rangle_0^{1/2} = K_{s,0} M^{1/2} \tag{A9}$$

Intrinsic viscosities $[\eta]$ are also controlled by the space requirements of polymer molecules. For unperturbed coils of linear chains, one can write (see textbooks of polymer science)

$$[\eta]_0 = \Phi_0(\langle s^2 \rangle_0/M)^{3/2} M^{1/2} = K_0 M^{a_v} \tag{A10}$$

where Φ_0 is usually assumed to be a universal constant (but see Ref. 498). The dependence of the radius of gyration, $\langle s^2 \rangle^{1/2}$, or the intrinsic viscosity, $[\eta]$, on the square-root of the molar mass is generally taken as a manifestation of unperturbed dimensions and thus also of the presence of the theta state of the polymer.

The assumption that theta conditions lead to unperturbed dimensions is often fulfilled within limits of error for most of the investigated polymers but it is not true in the general

sense. The thermodynamic definition of the theta state refers to the *global* properties of polymer solutions whereas the definition of unperturbed dimensions relates to the *local* properties of the chain. Both definitions agree *exactly* only if infinitely thin chains are surrounded by a locally and globally homogeneous continuum of solvent molecules.

The ability of a theta solvent to generate unperturbed dimensions thus depends on the constitution and configuration of the polymer, the solvent, and the temperature [83] since all these factors influence long-range interactions (excluded volume effects and interactions with the solvent). Small molar mass dependencies of theta temperatures are sometimes detectable for single solvents (230), especially at low molar masses when the effects of end groups or small helical segments (525) become noticeable.

However, if the macromolecules have long side chains and if the main chain and the side chains are constitutionally different, then the theta state of a polymer solution may not be identical with the unperturbed state of polymer coils, even for single solvents. An example is the solution of poly(octadecyl methacrylate) in butyl acetate which is in the theta state at 10.5°C ($A_2 = 0$). At this temperature, the exponent a_v of the intrinsic viscosity/molar mass relationship of Eq. (A10) was found as $a_v = 0.44$ instead of 0.50, due to a contraction of the long side chains (406). A similar discrepancy between the theta state of the polymer–solvent system and the unperturbed dimensions of the polymer coils has been found for cyclic poly(styrene) in cyclohexane where $\Theta = 28.5$°C according to thermodynamics but $a_v = 0.40$ at the same temperature; $a_v = 1/2$ was observed for the considerably higher temperature of $T = 40$°C (366). In both cases, intrinsic viscosities were assumed to reflect unperturbed dimensions. This is not necessarily true, however, since atactic poly(methyl methacrylate) exhibited the same reduced mean-square radius of gyration, $\langle s^2 \rangle_0 / \overline{M}_w$, in the two theta solvents acetonitrile ($\Theta = 44$°C) and *n*-butyl chloride ($\Theta = 40.5$°C) whereas the corresponding viscosity quantities, $[\eta]_\Theta / \overline{M}_w^{1/2}$, definitely differed from each other despite the almost identical theta temperatures (512).

In mixed solvents, these effects may be enhanced by a possible distribution of solvent components, depending on the polarities of the polymer 2 and liquids 1 and 3; 1 is a solvent and liquid 3 usually a non-solvent (precipitant). It seems that in the absence of large variations of theta temperatures, the unperturbed dimension of a given apolar polymer is approximately the same in various apolar solvents. However, unperturbed dimensions (as determined from intrinsic viscosities) may vary widely for polar polymers in various polar theta mixtures (31,95,154). For a review of various methods for the determination of unperturbed dimensions in mixed solvents see (526).

2. Methods to Determine Theta Solvents

Methods for the determination of theta temperatures are discussed in greater detail in two reviews (527,528). As mentioned above, theta conditions do not necessarily lead to unperturbed dimensions of coils (and *vice versa*).

2.1. Phase Equilibrium (PE) Binary mixtures of a polymer in a single solvent phase-separate at various temperatures, T_{sep}, depending on the volume fraction ϕ_2 of the polymer. The maximum of the $T_{sep} = f(\phi_2)$-function is called the critical solution temperature T_{cst}. The experiment is repeated for a series of dilute solutions of polymers of the same constitution and configuration but of different molar mass. The relation between the critical solution temperature and the molar mass of the polymer is based on the Flory–Huggins lattice theory which predicts that

$$\frac{1}{T_{cst}} = \frac{1}{\Theta}\left[1 + \frac{1}{\psi_1}\left(\frac{1}{r^{1/2}} + \frac{1}{2r}\right)\right] \qquad \text{(A11)}$$

where ψ_1 is the Flory residual-entropy parameter and r is the ratio of the molecular volume of the polymer to that of the solvent. Since r is proportional to the (number-average) molar mass of the polymer, Eq. (A11) can be written as

$$\frac{1}{T_{cst}} = \frac{1}{\Theta}\left[1 + \frac{b}{(\overline{M}_n)^{1/2}}\right] \qquad \text{(A12)}$$

for polymers of sufficiently high r (or $\overline{M}_n$) (Shultz–Flory method) (110,529). Extrapolation of the inverse critical solution temperatures to infinite molar mass delivers the inverse theta temperature Θ.

The data must be extrapolated not only to infinite molar mass but also to infinite dilution if used with mixed solvents (191). Furthermore, the method can be used only for phase separations into two liquid phases. Care must therefore be taken with crystalline polymers.

2.2. Second Virial Coefficient (A) All absolute methods for the determination of molar masses may be used; most commonly applied are membrane osmometry and static light scattering. Less frequently used are vapor phase osmometry and sedimentation equilibrium. Absolute methods that depend on specific solvent behaviour cannot be applied; examples are cryoscopy and ebullioscopy. Measurements must be performed at sufficiently low polymer concentrations in order to avoid effects of third virial coefficients.

The concentration dependence of reciprocal apparent molar masses is determined for a given polymer–solvent pair at different temperatures. Second virial coefficients are calculated from the slopes of these curves (see Eqs. (A6) and (A8)) and plotted against temperature (110). The dependence of the second virial coefficients on temperature is linear only in the proximity of the theta temperature. Care must be taken, therefore, to work close to the theta temperature. Alternatively, the second virial coefficient may be measured at a constant temperature, using different solvent–nonsolvent ratios. However, appropriate precautions and corrections have to be used if mixed solvents are

used (Donnan equilibria in membrane osmometry, effects of differences in refractive indices in static light scattering, etc).

2.3. *Cloud-Point Titration (CP)* Dilute polymer solutions of different concentrations are titrated at constant temperature with a nonsolvent until the first sign of cloudiness. The volume fraction $\phi_{3,\mathrm{cp}}$ of the nonsolvent 3 at the cloud point is then plotted against the logarithm of the volume fraction $\phi_{2,\mathrm{cp}}$ of the polymer at the cloud point (89,90,531) and extrapolated to pure polymer:

$$\phi_{3,\mathrm{cp}} = \phi_{3,\Theta} - B_{\mathrm{cp}} \ln \phi_{2,\mathrm{cp}} \qquad \text{(A13)}$$

where B_{cp} is the slope of the $\phi_{3,\mathrm{cp}} = f(\ln \phi_{2,\mathrm{cp}})$-curve and $\phi_{3,\Theta}$ is the volume fraction of the nonsolvent in the theta mixture solvent–nonsolvent. At high molar masses (small B_{cp}) and polymer densities $\rho_2 \approx 1$ g/ml, mass-concentrations $c_{2,\mathrm{cp}} = \rho_2 \phi_{2,\mathrm{cp}}$ (in g/ml) can be used instead of volume fractions $\phi_{2,\mathrm{cp}}$ (93); neglect of these conditions may lead to errors (58). This "Elias method" has been shown to have theoretical justification from the Flory–Huggins lattice model (532,533); a comprehensive review of this method is available (93).

2.4. *Cloud Temperature Titration (CT)* In a variation of the cloud point titration method, cloud temperatures may be determined by cooling or heating of dilute polymer solutions of various concentrations until cloudiness appears (58). The inverse cloud point temperature T_{ct} is then plotted against the logarithm of the volume fraction $\phi_{2,\mathrm{ct}}$ of the polymer 2 at the cloud point and extrapolated to pure polymer:

$$\frac{1}{T_{\mathrm{ct}}} = \frac{1}{\Theta} - B_{\mathrm{ct}} \ln \phi_{2,\mathrm{ct}} \qquad \text{(A14)}$$

This method is also based on the Flory–Huggins lattice model (522,533). In a modification of the method, inverse cloud temperatures are plotted against $1/r^{0.6}$ (530), again based on the Flory–Huggins theory:

$$\frac{1}{T_{\mathrm{ct}}} = \frac{1}{\Theta}\left(1 + \frac{B_{\mathrm{r}}}{r^{0.6}}\right) \qquad \text{(A15)}$$

where r is the ratio of molecular volumes of polymer and solvent.

2.5. *Unperturbed Dimensions (RGM, VM, DM, SM)* Root-mean-square radii of gyration, $\langle s^2 \rangle^{1/2}$, depend on the a_{s} power of the molar mass M (110):

$$\langle s^2 \rangle^{1/2} = K_s M^{a_s} \qquad \text{(A16)}$$

The exponent becomes $a_{\mathrm{s}} = 1/2$ for the unperturbed state where $\langle s^2 \rangle = \langle s^2 \rangle_0$. The temperature dependence of the function $\langle s^2 \rangle = f(M)$ can thus be used to determine the temperature T_0 at which $a_{\mathrm{s}} = 1/2$ (RGM method).

This method is cumbersome; more often used is the temperature dependence of the intrinsic viscosity/molar mass relationship

$$[\eta] = K_{\mathrm{v}} M^{a_{\mathrm{v}}} \qquad \text{(A17)}$$

because $a_{\mathrm{v}} = 1/2$ at the unperturbed state (at T_0) (VM method). Less often used are the corresponding relationships between molar masses and other hydrodynamic properties such as sedimentation coefficients (SM method) or diffusion coefficients (DM method).

Unperturbed radii of gyration (from scattering experiments) always seem to indicate theta conditions (cf. Ref. 512) but the database is too small to allow definite proof. Unperturbed dimensions from hydrodynamic measurements in single solvents sometimes do not coincide with the theta state (cf. Refs. 366,466,512); see also Section 1.2. Hydrodynamic measurements in mixed solvents very often deliver different unperturbed dimensions for theta conditions (cf. Refs. 31,83,95,154).

2.6. *Other Methods (IG, PL, R)* The theta state and/or unperturbed dimensions have occasionally been determined by various other methods: refractometry (R) (7,24), dielectric measurements (E) (5), polarized luminescence (PL) (399), inverse gas chromatography (IG) (412), and dynamic light scattering (LS) (376).

Common methods for the determination of theta temperatures Θ, theta compositions ϕ_i, Θ of mixed solvents, and/or unperturbed dimensions are compared in the following table:

Method		Required for the application			
Abbreviation	Name	Minimum number of polymers	Knowledge of molar mass	Type of solvent	Determined parameter
A	Second virial coefficient	3	Yes	Preferably single	Θ
CP	Cloud point titration	1	No	Mixed	$\phi_{3,\Theta}$
CT	Cloud point temperature	1	No	Preferably single	Θ
PE	Phase equilibria (critical solution temperature)	3	Yes	Preferably single	Θ
VM	Intrinsic viscosity/molar mass	3	Yes	Single or mixed	$\Theta, \phi_{3,\Theta}$

B. TABLES OF THETA SOLVENTS FOR POLYMERS

In the following tables, theta solvents and theta temperatures have been compiled for various polymers from the literature. The polymers are subdivided into groups of chemically similar compounds (see beginning of chapter for Contents). Within each group, polymers are arranged alphabetically, mostly according to the polymer names used in the original reference; no attempt has been made to use either IUPAC names (systematic names) or poly(monomer) names exclusively. Monomer units in alternating and random copolymers are listed alphabetically, regardless of their proportions; their relative amounts are given in parentheses on a mole/mole basis. Segments of block and graft copolymers are usually noted in the sequence reported by authors. The following abbreviations are used: *alt* (alternating), *block* (self-explanatory), *co* (statistical or random (or unspecified)), *graft* (self-explanatory).

Polymers are further characterized by their tacticity (if any), provided it has been reported in the literature. Polymers by free radical polymerizations are usually assumed by authors to be "atactic". Tacticities are usually given as mole fractions of isotactic diads (x_i), syndiotactic diads (x_s), isotactic triads (x_{ii}), syndiotactic triads (x_{ss}), heterotactic triads (x_{is}), *cis*-configurations (x_{cis}), *trans*-configurations (x_{trans}). If no quantitative characterization was reported, tacticities are described as it (predominantly isotactic), st (predominantly syndiotactic), at (neither predominantly iso- nor syndiotactic), cis (predominantly cis-tactic), or trans (predominantly trans-tactic).

For each polymer, theta solvents are given in alphabetical order; no attempt was made to convert commonly used solvent names into systematic names (e.g. dioxane = 1,4-dioxane). In mixed solvents, the liquid listed first may thus be a solvent or a nonsolvent. Compositions of mixed solvents are given in vol./vol. unless otherwise noted (ex: w/w indicates weight per weight).

A recent (smaller) list (496) of "Theta Temperatures" is mainly concerned with unperturbed dimensions. Since these dimensions are often evaluated from measurements at nontheta temperatures using various theories of intrinsic viscosity/molar mass, or (far less frequent) radius of gyration/molar mass relationships, reported "theta temperatures" are often not theta temperatures *per se* but the temperatures at which measurements in thermodynamically *good* solvents have been performed. A comprehensive list of unperturbed dimensions of various polymers can be found in Section VII/1 of this Handbook and a list of characteristic ratios of polymethacrylates in (497).

A. PRINCIPLES OF POLYMER FRACTIONATION

As a general rule, the composition of a polymeric substance is not homogeneous. The differences between the macromolecules of such a substance may be classified according to three main properties: (a) molecular weight, (b) chemical composition, and (c) molecular configuration and structure. Fractionation of a polymeric substance means the separation of that substance into its different molecular species, using a suitable experimental technique, in order to obtain homogeneous fractions. The molecular weight distribution is a general feature for practically all synthetic polymers; it is a consequence of the particular nature of the polymerization process by which they are made. Natural polymers usually have molecular weight distributions as a result of the degradation processes suffered by the substance during

Mr. J. Salort's data processing skills permitted the authors to prepare a draft of this chapter in a relatively short time, and they thank him for his invaluable help.

isolation from living tissues. Additional causes, such as more or less accidental degradation during processing, improper handling, or routine use, may contribute substantially to an increase in the width of the natural molecular weight distribution already present in the sample. The existence of molecular weight heterogeneity in macromolecular substances is therefore quite general. It is one of their fundamental properties and is directly responsible for the necessity of using several molecular weight averages for their description. It also exerts a permanent influence on all the properties of the substance, both in solution and in the solid state.

Differences in chemical composition in polymers originate from those reaction which offer several possibilities of substitution along the backbone of the macromolecules, for instance, the synthesis of random, block and graft copolymers and then any partial chemical transformations to which the substances can be subjected.

The third kind of heterogeneity mentioned above refers to differences in the physical configuration of the macromolecules, such as those between linear and branched polymers, and also to differences in the tacticity of the several molecular species present in the mixture, which is usually reflected in varying amounts of amorphous and crystalline materials in the substance.

Most of the experimental techniques developed so far to fractionate polymers refer to fractionation according to molecular weight. Chemical composition and physical structure differences are handled by more or less sophisticated modifications of the solubility method, such as varying the nature of solvent/nonsolvent mixture or the temperature of extraction, or by using an appropriate active support (adsorbent). The experimental techniques referred to in the tables are mostly based on the variation of some properties directly related to the molecular size. It is common to classify the fractionation method according to their preparative analytical character. The latter methods do not isolate fraction; they are mainly intended to explore the molecular weight distribution of the polymer. The classification of fractionation methods together with the basic idea of each experimental technique is briefly described below. Reviews of polymer fractionation have been published by Cragg and Hammerschlag (660), Desreux and Oth (745), Schulz (2902), Conrad (613), Hall (1198), Channen (544), Guzmán (1172,1174), Bello, Barrales-Rienda and Guzmán (276,277), Fuchs and Leugering (936), Kaesbauer and Schuch (1584), Screaton (2924), Schneider (2878), Cantow (506), Johnson, Porter and Cantow (1506), Moll (2231), Tung (3284,3286), Francuskiewicz (918). Reviews dealing with some specific aspects of fractionation have been published by Schurz (2915), Samsonov (2826), Schneider (2880), Giddings (1047, 1050–1052,1147). Reviews concerning theoretical aspects of polymer fractionation have been given in the book of Tompa (3217), and by Voorn (3397), Huggins and Okamoto (1392), and Koningsveld (1749).

In recent years, gel permeation chromatography (GPC) has become a technique of widespread use not only for molecular weight distribution but also for preparative fractionation. There exists much information on this technique in recent literature. General reviews on GPC have been published by Cantow, Porter and Johnson (505), Heitz and Kern (1262), Altgelt and Moore (71), Johnson and Porter (1507,1508), Altgelt (72), Determann (748), Altgelt and Segal (73), Lambert (1854), Ouano, Barrall II and Johnson (2492), Dawkins and Yeadon (717), Janča (1471), Ouano (2494), Barrales–Rienda (225), Bruessau (452), Hamielec and Styring (1202), Dawkins (718) and books by Yau, Kirkland and Bly (3552), Belenkii and Vilenchik (275), Janča (1474). Also, nonexclusion liquid chromatographies and cross fractionations for copolymers have been reviewed by Glöckner (1071,1076,1080), Vela Estrada and Hamielec (3366) and Mori (2283); temperature rising elution fractionation (TREF) by Wild (1710,3475, 3476); and field flow fractionation (FFF) by Janča (1476).

B. FRACTIONATION METHODS

1. Fractionation by Solubility

(a) Fractional Precipitation

Addition of Nonsolvent Successive precipitation of polymer species from a solution by addition of a miscible nonsolvent. The larger molecules precipitate first.

Lowering the Temperature Successive precipitation of polymer species from a solution by controlled cooling. The larger molecules precipitate first.

Solvent Volatilization Successive precipitation of polymer species from a solution of the polymer in a solvent/nonsolvent mixture by controlled evaporation of the more volatile solvent. The larger molecules precipitate first.

Pressure Variation at Lower Critical Solution Temperature Successive separation is carried out at a lower critical solution temperature (LCST) under isothermal conditions by changing the pressure of the system. Low molecular weight species are precipitated first. The efficiency of the method is poor in low molecular weight ranges.

(b) *Turbidimetric Titration* Continuous precipitation of polymer species from a very dilute solution by progressive addition of nonsolvent. In the absence of coagulation, the amount of polymer precipitated can be measured by the increase in optical density of the solution. The larger molecules precipitate first. This is an analytical method and can also be reversed, i.e; the polymer is first precipitated completely, and then redissolved by progressive addition of solvent.

(c) *Summative Precipitation* Simultaneous precipitation of polymer species from several solutions of the same sample by addition of increasing amounts of nonsolvent to the solution. The sum of all the precipitates constitutes a cumulative weight distribution. This is an analytical method.

(d) *Cumulative Volume of Precipitate* Successive precipitation of polymer species from a solution by addition of increasing amounts of nonsolvent. Fractions are not isolated

and the cumulative volume of precipitate is observed and determined after each nonsolvent increment. This is an analytical method.

(e) Fractional Solution

Direct Extraction Small polymer molecules are brought in direct contact with the solvent to extract low-molecular weight species from the swollen polymer. Subsequent fractions can be obtained either by different solvent mixtures of increasing dissolution power, or by raising the temperature stepwise with the same solvent. Smaller molecules are extracted first.

Film Extraction

CONTINUOUS OPERATION (CONTINUOUS FILM EXTRACTION) (CFE) The polymer solution is applied as a thin coating on both sides of a slowly moving belt. On passing through a drying region the solvent evaporates; the thin film on the belt is extracted continuously in a series of tubes containing solvent/nonsolvent mixtures of increasing dissolution power kept at constant temperatures.

BATCH OPERATION (FILM EXTRACTION) It works by using support material to obtain a very thin film with a large surface area. A metal foil is coated thinly with a polymer solution and the solvent is stripped out; after drying, the foil is cut into strips and extracted successively with solvent/nonsolvent mixtures of increasing solvent power, or by raising the temperature stepwise with the same solvent. Smaller molecules are extracted first.

Column Extraction The polymer is distributed on an inert support (small glass beads or sea sand) packed in a column which will subsequently have solvent passed through it either in an upward or downward direction. Successive elutions then take place in steps by the use of different solvent mixtures or by different extraction temperatures.

Temperature-Rising Elution Fractionation (TREF) The sample is loaded by injection in hot solution into a column packed with an inert support. The column is held in a hot bath. The loaded column is then cooled down to room temperature at a rate as slow as possible. The polymer to be fractionated must be deposited on the inert support by programmed cooling slow enough for crystallization, in such a way that it facilitates and promotes the crystallization of the different branched species in layers one upon the other. This step favours the effective separation by elution with increasing temperatures, which may be carried out stepwise or continuously. Therefore, polymer species are eluted with a solvent from the column as the temperature rises at a selected rate of heating. Molecules are eluted first according to their short-chain branches, i.e., with respect to degree of branching.

Coacervate Extraction A liquid polymer-rich gel phase (coacervate) is extracted by a solvent, forming a sol phase. Both the sol phase (or extracting agent) and the gel phase (coacervate) contain the same solvent and nonsolvent and are formed only together with the polymer fractionated (i.e., solvent and nonsolvent are completely miscible without the polymer). Thus, this procedure is a liquid–liquid extraction. Successive extraction of polymer species can be done from the coacervate. Smaller molecules are extracted first.

Continuous Polymer Fractionation (CPF) It represents a special variety of a counter-current extraction that functions in the following way: A comparatively concentrated solution of the polymer in a given solvent [it can also be a solvent/non-solvent mixture (the feed, FD)] is introduced into a pulsed sieve-bottom column at one end, and the same solvent or solvent/nonsolvent mixture but free of polymer (extracting agent, EA) is added at the other end. Both phases are homogeneous as they enter the column, but the CPF splits the polymer into two fractions by demixing inside the column in such a way that the molecules of different mass distribute between the two phases. This treatment really forms a coacervate due to the limited solubility of the polymer in the solvent/nonsolvent system. The coacervate is continuously extracted inside a counter-current column by the liquid extracting agent whereby the polymer molecules will be distributed over the counter-current phases according to their MW. The high molecular weight material remains in the phase resulting from the feed and leaves the column as the gel phase, whereas the low molecular weight material is extracted with the sol phase, so these two fractions leave the column as gel and sol phases, respectively. Thus, the original polymer can be split into two fractions at a desired MW in one continuous run.

(f) Partition Between Immiscible Solvents

Polymer species are distributed according to molecular size between two immiscible liquids of different solvent power. Counter-current extraction is particularly suitable for this method.

(g) Fractionation with Demixing Solvents

It is possible to separate chemically different polymers dissolved in a suitable homogeneous solvent mixture quantitatively, if the solvents are miscible at high temperatures but show phase separation at a lower temperature. Demixing is reached by slow-cooling the system to the desired separation (equilibrium) temperature. Stirring of the system is advantageous. Details of the demixing procedure depend on polymer species. Blends of polymers and copolymers, including block-, graft- and statistical copolymers, can be separated in one fractionation step with respect to their chemical nature. Multistep fractionation methods using demixing solvents (cumulative, successive, semicumulative, and head–tail type of fractionation) have been used to determine the chemical distribution of binary copolymers as well as block- and graft-copolymers.

(h) Fractional Crystallization

Successive separation of species from polymer solutions by crystallization at different temperatures. The crystallization can be carried out under stagnant conditions, but considerable improvement in the efficiency is obtained if the crystallization is induced by fast stirring (stirring crystallization). Under these conditions, the high molecular weight constituent crystallizes first, settling on the stirrer as long thin fibrillar crystals. The technique can be coupled with fractional

References page VII-438

extraction at increasing solution temperatures. The method is poorly reproducible.

Crystallization Analysis Fractionation (CRYSTAF) It is based on the segregation of crystals of different morphology or comonomer content by crystallization. In CRYSTAF, the separation and analysis are performed in a single step (the crystallization cycle), where concentration of the polymer solution is intermittently sampled and analyzed as the temperature goes down. The temperature–concentration data which are obtained correspond, in the cases of branched poly(olefins) or their copolymers with a-olefins, to the cumulative curve of the side chain branching distribution (SCBD). The last point at the lowest temperature of the experiment is the soluble or noncrystallizable fraction.

2. Fractionation by Chromatography

(a) Adsorption Chromatography (Chromatography on an active support) The adsorption of polymer species on an active support depends on the molecular weight.

Frontal Analysis The active support is packed in a column. A solution of polymer passes down the column and is collected when leaving it. The concentration in the effluent changes with the volume collected, and presents successive fronts due to the differential adsorption of molecular species on the active support.

Elution Analysis

COLUMN A small quantity of polymer is adsorbed on the upper portion of the support packed in the column. Elution with a suitable solvent takes place; each component moves down the column at a different rate and is completely displaced at some time and collect in the effluent; in the gradient elution method, the eluent is a liquid of increasing solvent power.

THIN LAYER CHROMATOGRAPHY (TLC) A thin layer chromatographic system is represented by the following three elements: a stationary phase which is a thin layer formed usually on a glass plate with an adsorbent like silica gel (the thin layer is activated by drying); a mobile phase which is any solvent or mixture used as a developer, and a sample. Separation is effected because the migration rate of each component relative to that of the mobile phase is retarded by the stationary phase to different degrees. A spot of the polymer solution is put on the plate, and after drying, the plate is placed vertically in a tank containing a suitable solvent or mixture. As the solvent moves upwards, it carries along each component at different rates. Separated, colorless species can be made visible by appropriate methods. When TLC is used in combination with a concentration gradient method, the composition of the developer (solvent or mixture) changes with the development time. In general, the TLC of a polymer may be classified into four types depending on the separation mechanism: adsorption–desorption, partition, molecular sieving (size exclusion), and ion-exchange process. However, only two of the above mechanisms, adsorption and molecular sieving, are applicable to separation of high polymers.

(b) Competitive Selective Adsorption This method is applied to separate mixtures of tactic forms into their components. The principle of separation consists of a competitive adsorption of two different tactic polymers from the solution onto solid surface. The two tactic forms compete for occupying active sites on the solid adsorbent; one of them will be selectively adsorbed on the adsorbent, while the second one will be unadsorbed and remain in solution. In practice, the separation is carried out by adding the solid adsorbent to the solution of the tactic mixture. The solvent must be selected in such a way that the stereocomplex formation between tactic forms rarely occurs.

(c) "Precipitation" Chromatography (Baker–Williams Method) (Chromatography on an inactive support) The support is an inert material packed in a column. On top of the column, a small amount of polymer is placed, as in elution chromatography. A temperature gradient is set along the column, the upper part being at higher temperature than the bottom; then the elution takes place with a solvent mixture of increasing solvent power. Polymer species move down the column being in a continuous exchange between a precipitated phase and a saturated solution. This distribution depends on the molecular size. Precipitation chromatography can also be carried out in the absence of a temperature gradient. It then becomes essentially a continuous fractionation by fractional solution. (see under Fractional Solution Column Extraction).

(d) Normal-Phase and Reversed-Phase Liquid Chromatography Copolymer separation by non-steric liquid chromatography (NELC) can be achieved in practice by the difference of adsorption power between the copolymers and the stationary phase. In both NPLC and RPLC, the mobile phase should be a good solvent for the copolymers during the entire elution.

In NPLC, stationary phases are polar, for example, silica gel, silica-CN, silica-NH_2 and poly(acrylonitrile) gel; retention times increases with sample polarity and mobile phases are less polar. Gradient elution is performed to increase the content of a polar solvent in the mobile phase, i.e. the polarity of the eluent increases in the course of a run.

RPLC is performed on non polar columns, i.e. stationary phases are hydrophobic (e.g. packed with crosslinked poly(styrene) (PS), or an alkyl branched phase materials such as silica-ODS), and the retention times decrease with polarity. Mobile phases are polar. RP gradient elution is performed to increase the content of less polar solvent in the mobile phase, i.e. the polarity of the eluent decreases in the course of a run.

(e) Gel Permeation Chromatography (GPC) (Chromatography on a porous support) Gel permeation chromatography, sometimes referred to as size-exclusion chromatography (SEC), is an analytical or preparative technique in which solute molecules are separated according to their effective hydrodynamic volumes in solution. A

gel permeation chromatographic system is composed of three fundamental elements. The stationary phase is an expanded and highly crosslinked polymer gel network (expanded silica gel, gel of porous glass, or some of these, but modified by chemical or physical treatments). The gel is packed into a chromatographic column; a mobile phase which may be any solvent or mixture for the polymer and a good swelling agent for the gel. The polymer sample in dilute solution is injected onto a column which contains porous particles with solvent and which is continuously fluxed with eluent. The separation occurs as the polymer molecules in the eluent solvent (mobile phase) percolate through the porous bed (stationary phase). As a result of the restrictions imposed by the size of the pores on the larger molecules, there is a greater pore volume available to the low molecular weight species giving them in effect a longer path length and they, therefore, are more strongly retarded during elution. In other words, small molecules are able to penetrate into the pores of the beads more readily than the larger ones. This effectively increases the retention volume as molecular size decreases. Hence an inverse relationship between retention volume and molecular weight of the polymer exists.

Since from an ideal point of view polymer solubility and adsorption are not occurring in this chromatographic process, the volume of eluent required for the elution of any macromolecules species must essentially be dependent on chain length and appears to be insensitive to structure (universal calibration). However, this seems to be not always the case (non-exclusion effects).

(f) Surface Exclusion Chromatography (Hydrodynamic exclusion chromatography) Conventional gel permeation chromatography (GPC) fails when applied to the characterization of very large macromolecules. Such polymers are easily oriented or deformed by hydrodynamic forces occurring in columns. Hence, steric pore exclusion mechanisms are disturbed, separation efficiency is poor, and the relationship between elution volume and molecular weight is no longer found valid for the highest molecular weight species.

Surface exclusion chromatography (hydrodynamic exclusion chromatography) has been developed for rigid particle size determinations. This technique has been shown to be efficient for size separation of proteins and latexes. It uses a non-porous packing as a stationary phase.

(g) Partition Chromatography Polymer species are distributed between two liquid phases, one of them mobile and the other fixed by absorption on a support. The support consists of strips or sheets of porous paper. The immobile phase is packed in a column.

(h) Phase Distribution Chromatography (PDC) Separation of polymer components in a PDC column is based on thermodynamic and kinetic interactions between the mobile phase (the polymer to be analyzed is dissolved in a Q-solvent) and a gel (stationary phase) of the same linear high polymer situated as a non-crosslinked coating on the surface of small glass bead. It is important to keep the temperature always below the Q-temperature of the sample. The separation efficiency increases sharply with decreasing temperature since the higher molecular species dissolve in the gel phase to a higher extent than the lower molecular species, the former leave the column later. It is a powerful method for the correct determination of narrow molecular weight distributions.

(i) Field Flow Fractionation (FFF) Field flow fractionation resembles chromatography in both the experimental and dynamical aspects of its operation, and it can therefore be thought of as a chromatographic method. It requires neither a stationary phase in the classical sense, nor the packing to support as is characteristic of chromatography. For this reason FFF has been described as one phase chromatography. Like chromatography, it is an elution technique used to separate components as they are transported through a column by a stream of solvent. The method is based on the difference between the flow rates in the center and near the column walls which obey Poiseuille's law. Retention is caused by an external field or gradient which forces the solute into narrow layers occupying the slow flow regions near the wall of an empty channel. Several types of FFF based on the type of force field applied have been developed.

Classical FFF

THERMAL FFF Thermal field flow fractionation (ThFFF) is a high-resolution separation method for a wide range of relatively non-polar polymers in suitable organic solvents. Certain polar macromolecules can also be fractionated by ThFFF in totally aqueous systems. ThFFF separations are carried out with a single mobile phase in a thin, open channel by applying a large thermal gradient across highly polished parallel plates between which a spacer is clamped. It is usually composed of two metallic blocks with highly polished surfaces. ThFFF separations are governed by two transport mechanisms acting in opposition: thermal diffusion, which is the movement of mass in response to a temperature gradient, and ordinary (Fickian) diffusion, which is the movement of mass in response to the concentration gradient established by thermal diffusion.

SEDIMENTATION FFF Either natural gravitational or centrifugal forces in the centrifuge serve as an effective field. The channel is usually coiled around the interior basket of a centrifuge rotor. This technique separates components on the basis of their mass differences.

ELECTRICAL FFF The altogether homogeneous field is induced by electrical current across the channel. Charged macromolecules interact with the field and are separated according to the ratio of electrophoretic mobility to diffusion coefficient.

FLOW FFF Flow field-flow fractionation separates according to differences in diffusion coefficients.

PRESSURE FFF Pressure field-flow fractionation (pressure FFF) and flow FFF are by nature very similar. In both

cases, it is the cross flow that represents the lateral field. The principal difference is that in flow FFF, the flow field is applied externally across the channel formed between two parallel plane membranes, whereas in pressure FFF, the lateral flow across the wall of a circular-cross-section capillary is initiated by an internal pressure drop in a liquid pumped along the semipermeable capillary.

MAGNETIC FFF Magnetic field-flow fractionation has been studied in only a few cases dealing with theoretical principles of the separation and retention of bovine serum albumin in the presence of nickel (II) ions in a magnetic field of 400 G and retention of metal oxides.

CONCENTRATION FFF Concentration field flow fractionation (concentration FFF) is the only FFF technique that could make use of a concentration gradient of a mixed solvent across the channel in order to induce effective chemical forces or chemical field.

SHEAR FFF Shear field-flow fractionation (shear FFF) has been proposed as a technique in which shear forces are responsible for migration perpendicular to flow. An internal shear force field is induced in the annular space between two concentric cylinders that are in relative rotational motion.

Focusing FFF

SEDIMENTATION-FLOTATION FOCUSING FFF In SFFFFF solute particles or macromolecules "sediment" or float in the density gradient of a liquid phase according to the difference between the local density of the liquid and that of the particle or macromolecule. At quasi-equilibrium, the solute species are focused in a thin layer at the position where the density of the environment is the same as the solute density.

ISOELECTRIC FOCUSING FFF The electrophoretic mobility of amphoteric macromolecules is a function of pH and is zero at the isoelectric point. This means that if a stable pH gradient is formed in the FFF channel due to an applied electrical field, the amphoteric solute under the influence of this field is focused into the position of the isoelectric point. In a steady state, this transport is balanced by ordinary diffusion.

(j) Ion-Exchange Chromatography The support is an ion-exchange resin, constituting an immobile phase, through which the solution of polymer is passed. This method is appropriate for polymer species bearing electric charges; the molecules are distributed between the liquid phase and the interface, according to their ionic adsorption forces, which depend on the electric charge and the size of the macromolecules.

(k) Hydrodynamic Chromatography Hydrodynamic chromatography (HDC) is a rather new technique for separating solutes or dispersed materials at high dilution in the micron range, according to decreasing size. It is based on the effect of a radial flow gradient inducing different mobilities according to size. Larger particles are located preferentially in the axis of capillaries where the flow rate is maximum; whereas smaller ones are closer to the walls where the flow rate is minimum. Packed and open capillary columns can separate particles below and above one mm, respectively. It involves injection of a dilute latex sample into a carrier stream (the aqueous eluent) which is pumped through the system at a constant flow rate. The column is packed with non-porous beads. Larger particles exit the column before smaller ones and are detected using a suitable system of detection. It is a complementary method to field-flow fractionation (FFF), steric exclusion chromatography (SEC) and superfluid chromatography.

3. Cross Fractionation

Most of the copolymers and polymers obtained by chemical modification reactions generally possess a two-dimensional distribution: MWD (Molecular Weight Distribution) and CCD (Distribution of Chemical Composition). An analogous problem exists with polyolefins: MWD and distribution of Short-Chain Branching (SCB). It is normally impossible that they can be adequately fractionated by both molecular weight (MWD) and by chemical composition (CCD). The problem is overcome by cross fractionation. The term cross-fractionation refers to any combination of fractionation methods capable of evaluating the distribution in size and composition.

(a) Classical Cross Fractionation Cross fractionation requires two solvent/nonsolvent systems to separate in two different directions. A solvent/nonsolvent combination fractionating solely by MW would be appropriate for the evaluation of the MWD, another one separating by CC would be suited for measuring the CCD of the material. Fractions of the starting material obtained by one precipitant are redissolved and fractionated once more with the help of the complementary precipitant yielding the final fractions. Owing to its high expenditure of time and materials, classical cross-fractionation is seldom performed. However, this procedure is irreplaceable for the production of narrow molecular weight distribution fractions in both MW and CCD on a preparative scale.

(b) Non-Classical Cross Fractionation This technique of cross fractionation can be performed off-line or on-line. Typical cross-fractionations include partition chromatography-SEC, gradient elution-SEC, SEC-turbidimetric titration, gradient elution-TREF, TREF-SEC and demixing fractionation-demixing fractionation.

(c) Orthogonal Chromatography This technique is a special case of non-classical cross fractionation in which two coupled SEC techniques are used. SEC in different eluents can separate a copolymer in two diverging directions. Two SEC instruments are coupled together so that the eluent from the first one flows through the injection valve of the second one.

(d) Cross Fractionation by Bidimensional TLC Combined types of TLC are often for the separation of polymers, copolymers, etc. This technique allows separation according to chemical composition, molecular weight, and stereoregularity. Copolymers, LD and LLD poly(ethy-

lenes) and chemically modified polymers are extremely multicomponent materials which often exhibit simultaneous distributions of molecular weight, composition, and monomer sequence length. Interference of the remaining two distributions while attempting to elucidate one of them greatly complicates analysis. Cross fractionation (bidimensional) TLC is a method to elucidate such problems.

4. Fractionation by Sedimentation

(a) Sedimentation Velocity Sedimentation velocity of polymer species in a high centrifugal field is a function of molecular size. This is usually an analytical method unless a velocity ultracentrifuge of the preparative type is used.

(b) Sedimentation Equilibrium At lower rotational speeds of the ultracentrifuge, it becomes possible to create an equilibrium situation such that the rate of sedimentation is exactly equal to the rate of back-diffusion of the macromolecules. Larger polymer molecules are then found closer to the bottom of the cell than smaller ones.

(c) Density Gradient Technique In a performed or self-generated density gradient, the polymer collects around the position of its own density in a band. The width of this band is dependent on the molecular weight of the polymer. A band of polydisperse macromolecules contains more high-molecular-weight polymer near its maximum than near its "tails". This technique is also capable of separating according to composition.

5. Fractionation by Diffusion

(a) Thermal Diffusion A polymer solution is placed between two surfaces, and a high temperature gradient is established between them. The solution is in contact with an upper and a lower reservoir. The temperature gradient gives rise to a thermal circulation of the molecules, producing a separation of polymer species, which migrate towards the lower reservoir. Thermal diffusion is more pronounced for the larger molecules than for the smaller.

(b) Brownian Diffusion Polymer molecules diffuse at different rates from a solution into a solvent by a boundary, depending on their molecular weights. The translational diffusion constants can be determined by special optical means and related to the inhomogeneity of the sample. This is an analytical method.

6. Fractionation by Ultrafiltration Through Porous Membranes

A polymer solution is submitted to ultrafiltration through a series of membranes of different porosity. The rate of diffusion depends on the molecular size and the degree of permeability of the membranes. It is possible to isolate fractions with varying molecular weights at different times.

7. Fractionation by Zone Melting

A solid solvent is packed in a column. A small amount of polymer is put on top of the solid solvent and dissolved by heating a narrow zone. After solidification, a lower zone is heated, melted, and resolidified. The full column is treated in this way. Polymer species move down the column at different rates, depending on their molecular size during the molten stage. At the end, the polymer is distributed throughout the entire column and recovered by cutting the solid into several portions and sublimating the solvent.

8. Electron Microscopic Counting Method

With most glassy amorphous polymers, it is possible by means of the electron microscope, to observe single spherical molecules, if very dilute solutions in a solvent/nonsolvent mixture are sprayed onto a thin substrate. Consequently, the weight- and number-average molecular weights and molecular weight distributions can be obtained. The method can be recommended and applied only for polymers with molecular weights higher than 5×10^5.

C. TABLES OF FRACTIONATION SYSTEMS FOR DIFFERENT POLYMERS

TABLE 1. MAIN-CHAIN ACYLIC CARBON POLYMERS

Polymer	Method of fractionation	Solvent or solvent/nonsolvent mixture	Remarks	Refs.
1.1. POLY(DIENES)				
Poly(diacetylene)	Chromatography	Chloroform	SEC, styragel	2640,3450
			SEC, ultrastyragel	1677
		Methylene dichloride	SEC, μ-styragel	2620

		Tetralin/diethylene glycol monomethyl ethyl ether	Column elution, 145°C	2265
		Trichlorobenzene	SEC, 135°C,130°C,150°C	607,673,1774, 2487,2488,3377

TABLE 1. *cont'd*

Polymer	Method of fractionation	Solvent or solvent/nonsolvent mixture	Remarks	Refs.
		Trichlorobenzene/dimethyl phthalate	Precipitation chromatogr. temp. grad. 55–125°C glass beads	169
	Coacervation	*o*-Dichlorobenzene/triethylene glycol	Isotactic	191
		Tetralin/poly(oxyethylene)	140°C	2720
	Extraction		17 Hydrocarbon fractions with increasing b.p. from 35 to 130°C	2337
		Acetone, ethyl ether, *n*-pentane, *n*-hexane, *n*-heptane, *n*-octane	Isotactic	1956,2201,2372,2797
		Boiling (acetone, ethyl ether, *n*-hexane, *n*-heptane	Amorphous and crystalline	958
		Boiling (heptane, xylene)	Tacticity	536
		Boiling diethyl ether, hexane, heptane	Tacticity	479
		Boiling heptane, octane	Tacticity	213
		Boiling hexane, heptane, toluene	Syndiotactic	185
		Boiling xylene	Tacticity	536
		Boiling xylene, octane	Tacticity	535
		Boiling (ethyl ether, *n*-heptane, methyl cyclohexane)	Amorphous and crystalline	3351
		Different solvents	Different temp.	1539
		Ethyl ether, *n*-hexane, *n*-heptane	Syndiotactic	2438
		Heptane	Boiling	1970,3032,3252
			Hot and cold	892
		Heptane, diethyl ether, hexane/heptane	Kumagawa extraction	478
		Heptane, *n*-octane, xylene	Tacticity	2536
		Hexane	Boiling	2751
		n-Octane, *n*-heptane, *n*-hexane, *n*-pentane	Stereoregular separation	2539
		Xylene/ethylene glycol monoethyl ether		2674
	Fractional crystallization	1,2,4-trichlorobenzene	CRYSTAF, isotactic + sindiotactic mixture	2236
		n-Heptane	Stirred, opt. act. (amorphous and crystalline)	2500
		o-Xylene		341
		Octane	Lowering temp.	2539
		Perchloroethylene	70–90°C, isotactic	2560
		Xylene	Stereoregular separation	1550
	Fractional precipitation	Benzene/acetone		906
		Benzene/methanol	Atactic	293,1679
		Cyclohexane/acetone	Atactic	1681,2252
		Cyclohexane/isopropanol		124
		Cyclohexanone/ethylene glycol or dimethyl phthalate	Isotactic, 130–135°C	1681
		Decalin/phenol–decalin/ propylene glycol	130°C, nitrogen atm.	1870
		o-Dichlorobenzene/benzyl alcohol		2264
		Trichlorobenzene/dimethyl phthalate	140°C	169
		Xylene/poly(oxyethylene)	112°C,134°C	704,1557
		Xylene/triethylene glycol	130°C	2974
	Fractional solution	17 Hydrocarbon fractions with increasing b.p. from 35 to 130°C		
		Acetone, diethyl ether, *n*-pentane, *n*-hexane, *n*-heptane	Extraction	1940

TABLE 1. *cont'd*

Polymer	Method of fractionation	Solvent or solvent/nonsolvent mixture	Remarks	Refs.
		Acetone, diethyl ether, *n*-pentane, *n*-hexane, *n*-heptane	Extraction, anisotactic	2752
		Butyl cellosolve/diethyleneglycol monobutyl ether	165°C	1360
		Decalin	Rising temp.	2435
		Decalin/2-ethoxyethanol	Column extraction,110°C	1416
		Decalin/acetophenone	Column elution,146.5°C	2556
		Decalin/benzyl alcohol	Column elution,152°C	2556
		Decalin/diethylene glycol monobutyl ether	Column elution,161°C	2434
		Decalin/ethyl carbitol	Column elution,160°C	2435
		Diethyl ether, pentane heptane, aliphatic hydrocarbons, decalin	Successive extraction	1907
		Ether, hexane, heptane		609
		Ethylene glycol monobutyl ether/diethylene glycol monobutyl ether	Gradient extraction several temp.	1907
		Hexane, *n*-decane		1684
		Kerosene/diethylene glycol monomethyl ether	Column extraction,150°C	3350,3467
		Kerosene/diethyleneglycol monobutyl ether	Column elution,155°C,160°C	1420,2433
		Kerosene/ethylene glycol (10%) in 2-butoxyethanol	Column extraction 156°C, isotactic	673,872,2983
		Nine solvents of increasing solvent power and boiling point	According to crystallinity	2385
		o-Dichlorobenzene/diethylene glycol	Column elution, 168°C, 170°C and 172°C	704,1329,2137,2649
		o-Dichlorobenzene/diethylene glycol monobutyl ether	Column elution,166°C	3517,3518
		o-Dichlorobenzene/dimethyl phthalate	Column elution,150°C	2933
		Tetralin	Column extraction, increasing temp.	3016
		Tetralin/2-butoxyethanol	Column extraction	3146
		Tetralin/2-ethoxyethanol	Column extraction,170°C	2519
		Tetralin/diethylene glycol monomethyl ether–ethylene glycol (75%–25%)	Column extraction,180°C, isotactic	1312
		Tetralin/dimethyl phthalate	Column extraction,155–178°C	2161
		Xylene/2-ethoxyethanol	165°C	1359
		Xylene/ethylene glycol monoethyl ether	Gradient extraction, several temp.	1907
		Xylene/ethylene glycol monoethyl ether, ethylene glycol monobutyl ether/diethyleneglycol monobutyl ether	Temperature (121–128°C) and (159–161°C)	536
		Xylene/methanol	Column extraction, 56°C, atactic	2649,2983
		Xylene/poly(oxyethylene)	Coacervate extraction,134°C	704
	TREF	Trichlorobenzene	140–30°C	3026
		Xylene	20–130°C, column extraction	1536
			25–130°C, glass beads	2216
	Turbidimetric titration	Benzene/methanol	30°C, atactic	1522
		Chloroform/isopropanol	30°C, atactic	1522
		Tetralin/butyl cellosolve	110°C	3145,3146
Poly(propylethylene)	Fractional precipitation	Toluene/methanol	30°C, isotactic	696,2262
Poly(tetradecylethylene) *Poly(1-hexadecene)*				
	Chromatography	Trichlorobenzene	SEC, styragel, 80°C	3418

		Propio-,butyr, isobutyr-, and isovaleraldehydes	Amorphous + crystalline	2368
Poly(β-allyloxypropionaldehyde)				
	Chromatography	Tetrahydrofuran	SEC, styragel	137
Poly(aryl ether isoquinoline)s	Chromatography	Chloroform	SEC, μ-styragel	3004
Poly(1-butene oxide), see Poly(oxy(ethylethylene)				
Poly(epichlorohydrin), see Poly(oxy(chloromethyl)ethylene)				
Poly(epoxides)	Chromatography	Benzene	SEC, styragel	1263
Poly(ether ether ketimine)	Chromatography	Tetrahydrofuran	SEC,μ-styragel, 35°C	2778
	Fractional precipitation	Benzene/*n*-hexane	20–35°C	2778
Poly(ethylene oxide), see Poly(oxyethylene)				
Poly(glutaraldehyde)	Chromatography	Dimethylformamide	SEC, styragel	2038
Methyl [poly(ether ether ketone)]				
	Fractional precipitation	*N*-Methyl-2-pyrrolidone + chloroform/methanol	Hot dissolved in NMP and diluted in chloroform	3417
Poly(2-methyl-1,4,6-trioxa-spiro-(4,4)-nonane)				
	Chromatography	Tetrahydrofuran	SEC,μ-styragel	3226
Poly(*cis*-1,4-bis((methylsfulfonyl)methyl) cyclohexane),(*trans*-1,4-bis(methylsulfonyl)methyl)cyclohexane)				
	Chromatography	Chloroform	SEC, styragel, 40°C	2566
Poly[1,3-bis(1-naphthoxy)benzene]				
	Chromatography	Chloroform	SEC, styragel, 40°C	2567
Poly[2,2′-bis(1-naphthoxy)biphenyl]				
	Chromatography	Chloroform	SEC, styragel, 40°C	2567
Poly[4,4′-bis(1-naphthoxy)biphenyl]				
	Chromatography	Chloroform	SEC, styragel, 40°C	2567
Poly(oxadiazo-3,5-diyl-perfluoroethylidene-*block*-oxyperfluoropropylene)				
	Chromatography	1,1,2-Trichloro-1,2,2-trifluoroethane (Halocarbon 113)	SEC, porous silica	1765
Poly(oxy-2-butenyleneoxy-1,4-phenyleneisopropylidene-1,4-phenylene)				
	Chromatography	Tetrahydrofuran	SEC, styragel, 30°C	2324
Poly(oxy(*tert*-butyl)ethylene)	Fractional crystallization	Benzene	80°C, lowering temp.	53
	Fractional precipitation	Benzene/methanol		764
Poly(oxy(4-chlorobutyl)ethylene)				
	Cromatography	Tetrahydrofuran	SEC, styragel	2966
Poly(oxy(2-chloroethyl)ethylene)				
	Chromatography	Tetrahydrofuran	SEC, styragel	2966
Poly(oxy(chloromethyl)ethylene)				
	Extraction; precipitation	Acetone(cold), acetone/methanol, methanol/water		1431
Poly(oxy(3-chloropropyl)oxirane)				
	Chromatography	Tetrahydrofuran	SEC, styragel	2966
Poly(oxy-2-cyanoethyloxymethylene)				
	Fractional solution	Acetone, dimethylformamide		3097
Poly(oxy-1,2-cyclohexylene)	Chromatography	Tetrahydrofuran		1240,1241
	Fractional precipitation	Benzene/methanol	25°C	2128
Poly(oxy-1,4-cyclohexylene) *(poly(1,4-cyclohexane oxide)*				
	Chromatography	*m*-Cresol-chlorobenzene (1 : 1)	SEC, 25°C	3073
		Tetrahydrofuran	SEC,μ-styragel	319
Poly(oxy-3,5-dimethyl-1,4-cyclohexylene)				
	Chromatography	Tetrahydrofuran	SEC, styragel	1754
Poly(oxy-2,6-dimethyl-1,4-phenylene)				
	Chromatography	Carbon tetrachloride/methanol (98/2)	TLC, silica gel	2785
		Chloroform	SEC, styragel	120,3219
		Dimethyl sulfoxide	SEC	1932
		Methylene dichloride	TLC, silica gel	2785
		o-Dichlorobenzene	SEC, 80°C	1391
			SEC, styragel, 140°C	3320
		Tetrahydrofuran	SEC	2724,3460
			SEC, μ-styragel	2564
			SEC, μ-styragel, 40°C	230
		Toluene	SEC	31
	Fractional precipitation	Benzene/methanol		120

TABLE 3. *cont'd*

Polymer	Method of fractionation	Solvent or solvent/nonsolvent mixture	Remarks	Refs.
		Chloroform/methanol	20°C, preparative	217,1871,2504
		Ethylene dichloride/nitromethane		3061
		Toluene/methanol	20°C, preparative	217,220,1871
		Toluene/petroleum ether		152
	Fractional solution	Chloroform/acetone		3320
		Chloroform/methanol	Column extraction	456
	Stirring fractionation	Dioxane		31
	Turbidimetric titration	Chloroform/ethanol	25°C	456
Poly(oxy-1,1-dimethyltrimethylene) *[(Poly(2,2-dimethyloxacyclobutane)]*				
	Chromatography	Tetrahydrofuran		1758
Poly(oxy-2,2′-dimethytrimethylene) *Poly(3,3′-dimethyloxetane)*				
	Fractional precipitation	Chlorobenzene/ethanol		1099
		Cyclohexane/ethanol	30°C	2577,2579
Poly(oxy-2,6-diphenyl-1,4-phenylene)				
	Chromatography	Benzene	50°C	2981
		Methylene dichloride	25°C	1517
		Tetrahydrofuran		1087
Poly(oxy(ethylethylene) *poly(1-butene oxide)*				
	Chromatography	Tetrahydrofuran	SEC, styragel	27,1889,2009
		Trichlorobenzene	SEC, 90°C	389
	Fractional precipitation	Benzene/methanol		389
Poly(oxy(2-hydroxytrimethylene)oxy-1,4-phenyleneiopropylidene-1,4-phenylene)				
	Chromatography	Chloroform	SEC,μ-styragel	455
		Chloroform/ethanol (2/1)	SEC, Sephadex	245
		Tetrahydrofuran	SEC, butyl methacrylate gel	1843
			SEC, styragel	819,847,1843
	Fractional solution	Chloroform/*n*-hexane	Column extraction	2322
Poly(oxy-3-methyl-3-chloromethyltrimethylene)				
	Sedimentation velocity	Butanone	21°C	36
Poly(oxy-2-methyl-1,4-cyclohexylene)				
	Chromatography	Tetrahydrofuran	SEC	1754,1755
Poly(oxy(1-methyl)trimethylene)				
	Chromatography	Tetrahydrofuran	SEC, styragel	1756,1757,2441
Poly(oxy(2-methyl)trimethylene)				
	Fractional precipitation	Chloroform/methanol	25°C	2739
Poly(oxy-4-phenylazo-1,2-phenylene)				
	Chromatography	Tetrahydrofuran	SEC, styragel	2312
Poly(oxydecamethylene)	Fractional precipitation	Benzene/methanol		3523
Poly(oxyethylene)	Chromatography	Acetone	SEC, Sephadex, 50°C	1520
		Benzene	SEC, styragel	1263
		Butanone/water (1/1)	TLC, kieselgel	465
		Chloroform/ethanol (10/1)	TLC, alumina	978
		Chloroform/pyridine(5/7)	TLC, silica gel	978
		Dimethylacetamide	SEC, 74°C	1813,1822
		Dimethylacetamide	GLC of trimethylsilyl ether derivatives, low MW	898
		Ethylene glycol/methanol (4/1)	TLC, gradient const.	2480
		Methanol followed by methanol/dimethylformamide (4/1)	Gradient elution, TLC	2480
		o-Dichlorobenzene	SEC	3437
			SEC, 130°C	1251,1252
		Pyridene–water (0.1 : 10)	TLC, silica gel	978
